in severity or cease entirely as the typical ataxic symptoms appear. Dyspepsia is seldom present in tabetics who suffer from gastric crises. These crises should be differentiated from those of neurasthenia and hysteria, from the painful vomiting and colic of lead poisoning, and from the pains resulting from gall-stones or renal calculi. "To me it appears most likely," adds Professor Ewald, "that the gastric crises are due to auto-intoxication characterised by the presence of a toxin which has no influence upon normal nerves but which readily produces a state of irritation on the (sensory) nerves whose integrity has been impaired" in tabes dorsalis. No drugs can cut short an attack, though some little relief is obtained by the administration of antipyrin, erythrol tetranitrate, or cerium oxalate. In grave cases morphia has to be given hypodermically to alleviate suffering, but care must be taken that the patient does not become addicted to the morphia habit. Professor Ewald says that the injection of a few drachms of an anæsthetic mixture (cocaine hydrochloride, one and a half grains; sodium chloride, three and a half grains; and water to three and a half ounces) into the intradural space of the spinal cord is attended with relief of pain in severe cases.

THE SUPPLY OF VACCINE LYMPH IN SCOTLAND.

THE memorial which was submitted to Lord Balfour on July 15th deserved a reception different from the one which it encountered. As mentioned in THE LANCET of July 18th, p. 180, it pointed out that the various enactments relative to vaccination in Scotland contained no provision for the supply of glycerinated calf lymph and it therefore asked that the Government should establish in Scotland an institution for the preparation of calf lymph which might be distributed gratuitously to medical practitioners under such regulations as might be considered necessary. No one but an anti-vaccinationist would deny that the request was reasonable. Neither could anyone condemn it as impracticable, because the manufacture of lymph in official laboratories and its gratuitous distribution by the Local Government Board have been practised on a large scale in England for more than two years. Lord Balfour, in his reply, went over the whole ground conscientiously in ample detail, but he gave the deputation no encouragement. His observations might with perfect correctness be summed up in a few words by saying that the memorialists asked for lymph and received a lecture instead. "Memorial inaccurate and misleading," "not a fair way of presenting the case," "no substantial complaint made or proved against the lymph now in Scotland at the present time," "quotations not accurate," and so on, together with some rhodomontade about the risk of destroying the "structure of a system which is giving confidence to the people of Scotland." All these criticisms appear to us to be nothing more than the floundering of a perplexed politician unwilling to disturb the existing order of things and nettled by the discovery that a few medical men have ventured on the policy of Oliver Twist and are actually asking for more—not for themselves personally, be it remembered, but for the community at large. Persons holding public positions must not feel aggrieved if they are judged according to the inferences which may reasonably be drawn from their official utterances and if their treatment of great public questions is viewed by the public broadly and without minute attention to unimportant details. In some respects his lordship's criticisms of the memorial appeared so remarkable that before venturing to comment on them we not only re-read the lengthy account of the proceedings furnished by our own representative who was in attendance, but we also perused the reports of our contemporaries the *Scotsman*, the *Glasgow Herald*, and the *Times*, all four of which were found to be sufficiently in agreement. In brief, then, the memoria asked for a supply of glycerinated calf lymph because it ha certain advantages over humanised lymph and arm-to-ar vaccination. It was impossible that any persons could b found who had a better knowledge of every detail of th subject than the memorialists themselves and yet th Secretary of State, without in set terms professing t be an expert in vaccination, told them that no substantia complaint had been made or proved against the lymp which was actually used in Scotland at the present time This may be an excellent maxim in law and in many of th casual circumstances of daily life, but it is totally in applicable to a progressive science and art such a medicine or surgery, and if this policy were adopted b men of genius no advancement would be possible. Wa there any "substantial complaint made or proved" agains attempting a diagnosis in thoracic disease before Laenne invented the stethoscope or in disease of the eye befor Helmholz introduced the ophthalmoscope? Was there "substantial complaint made or proved" against cinchon bark before Pelletier isolated quinine? An infinity o analogies in the mechanical arts will suggest themselves t everybody. Then as to vaccination by public officials. H told the deputation what it already knew very well—that i England the public vaccinators vaccinate 56 per cent. of th children (of course with glycerinated calf lymph), while i Scotland the parochial vaccinators vaccinate only 2 per cent. This was used as an argument against the memorialists, wh were informed that they had no cause of complaint becaus in England, just as in Scotland, the lymph is not supplied t private practitioners. No one in the room could have failed to perceive that this was a mere juggling with words, for i England any parent who may desire it (even a Secretary of State) is entitled to have his child vaccinated gratuitously by the public vaccinator. The memorial did not go so fa as this, it did not ask for the appointment of official vaccinators remunerated out of the public rates, it merely asked for a gratuitous supply of lymph. To take only one more instance. Lord Balfour in congratulating his countrymen on the high proportion of the successful vaccination of infants seemed to have overlooked the pressing necessity that exists for encouraging revaccination and conveniently to have forgotten that Baillie Graham had just told him that in a recent epidemic of small-pox[1] the municipality of Glasgow spent £4500 in the purchase of lymph for revaccination, some of which had to be obtained from Paris.

FRACTURE-DISLOCATION OF THE CERVICAL SPINE WITHOUT PARALYSIS.

WE have lately had an opportunity of seeing at St Thomas's Hospital a very extraordinary case of fracture-dislocation of the cervical spine not associated with paralysis and, in fact, only discoverable by the x rays. The patient, a man, aged 56 years, fell down the stairs in his house a month before admission. He struck the back of his head on the wall at the bottom of the stairs and forced his head forwards, the chin being driven into the sternum. He got up and resumed his work on the next day and continued to work for a fortnight afterwards. He then came under the care of Mr. H. A. Easton who examined him with the x rays and found a fracture of the upper cervical spine. This was so unusual in the absence of symptoms that he sent him to Mr. W. H. Battle. The man complained merely of a stiff neck and of some pains at the back of the head and shoulders. There was no paralysis. The neck was held forwards stiffly and appeared to be thickened. A skiagram showed a fracture through the body of the axis with displacement of the body of that bone and the atlas forwards. The case was shown at a recent meeting of the Clinical Society of London and we understand that the subject will be brought forward at an early meeting of the society in October. We hope that this will be done as we have cognisance of other concealed fractures of the spine of somewhat similar character. They are very important from a medico-legal aspect and are not simply clinical curiosities. The high position of the fracture and displacement of the fragments without paralysis make this case unique.

[1] THE LANCET, August 16th, 1902, p. 452.

THE NEW SYDENHAM SOCIETY.

WE are requested to remind our readers that the annual meeting (the forty-fifth) of the New Sydenham Society will be held at Swansea next week. It will take place in the board-room of the Higher Grade School on Friday, July 31st, at 9 A.M. Mr. Henry Power, the treasurer, will occupy the chair. Not only the members of the society but all who are interested in its objects are invited to attend.

THE VON PETTENKOFER MEMORIAL FUND.

IT is proposed to erect to the memory of von Pettenkofer a marble statue of double life-size in Munich and towards this object £89 have been collected in Great Britain. The balance of this sum, after deducting £5 for the expenses of printing and postage, has been sent to the Bürgermeister of Munich who, through Dr. Christopher Childs, the honorary secretary and treasurer of the fund, desires to offer his warmest thanks to all those who have assisted in providing a contribution in Great Britain. We are pleased to know that some of our profession have so readily responded to the appeal for contributions towards this fund, but we had hoped that the total sum collected in Great Britain would have exceeded £89.

THE EPILEPTIC COLONY AT CHALFONT ST. PETER, BUCKS.

THE tenth annual report which has just been issued by the National Society for the Employment of Epileptics refers to the administrative and medical aspects of the epileptic colony at Chalfont St. Peter, Bucks, and to the general history of the colony during the year 1902. This institution has accommodation at present for 170 inmates, but the report points out that there is urgent need for the building of additional homes or villas at the colony to meet the increasing demands of cases seeking admission. A special convalescent home has just been erected and completed to receive casualties and sick cases occurring in the colony. The general health and progress of the "colonists" during the year have been eminently satisfactory; in fact, since the summer of 1897—a period of six years—there has been no death at the colony. The occupations and industries in which the inmates are employed include basket-making, laundry- and needle-work (for females only), carpentry, plumbing and painting, tailoring, boot-mending, and farm and garden work. The members of the honorary medical staff state in their report that 72 new patients (48 males and 24 females) were received at the colony during the year and that 36 patients (23 males and 13 females) left or were discharged as improved or partially recovered. With the extension of the colony, both in size and usefulness, the methods available for educating and employing the inmates have also increased. The present report confirms the view put forth in previous reports that the colony system as adopted at Chalfont St. Peter is of especial advantage in the training of young adult epileptics, both male and female. The colony as it now stands comprises 210 acres of farming land, gardens, and orchards, homes, workshops, and other buildings, representing a capital cost of over £40,000. By scrupulous economy in working and by the generous aid of friendly donors its work during the past few years of its existence has been accomplished without incurring debt. Full particulars as to the mode of application for candidates for admission as colonists and all information connected therewith are contained in a pamphlet entitled "Information for Applicants and their Friends," copies of which may be obtained from the secretary, Mr. G. Penn Gaskell, 12, Buckingham-street, Strand, London, W.C., who will also give information regarding intended gifts and bequests to the society.

THE SOILING OF FABRICS BY THE USE OF FLUID DISINFECTANTS.

THE free use of fluid disinfectants in houses in which infectious disease exists, or is suspected to exist, is a universally established practice and there can be no doubt of its value. One unsatisfactory feature, however, in connexion with the use of disinfectants is that some of them, at any rate, are not only greatly deficient as regards their active antiseptic ingredients but they are apt when used freely, and especially the phenol preparations, to leave indelible stains on sheets, blankets, and other fabrics. This is a serious matter to the poor householder whose means are often sadly strained to meet the expenses of a sick room. Stains on blankets and on sheets are very objectionable and present an unsightly and spoiled appearance which considerably discounts the value of the bed-clothing. Furthermore, stains on bed linen, &c., not unnaturally suggest an unpleasant association with infectious disease. It is desirable, we think, that all manufacturers of disinfectants should be compelled to make a statement as to the percentage of the active ingredient contained in their preparations and they should also ascertain that the disinfectant when properly used leaves no stains on fabrics. We have examined a number of preparations which comply with these requirements; they are efficient germicides and do not stain. It is only a matter of careful preparation, especially in the case of the alkaline mixtures, which, however, often contain little else than inert tar compounds. We may also draw attention to the miserably weak liquor of which the sanitary authorities are in the habit of distributing samples; they are often objectionable in appearance and offensive in odour, to say nothing of being practically worthless as germicides. Of course, it is important that a fair price should be paid for a really active fluid which could be diluted by the sanitary officers to a convenient and efficient strength. In this way the officials could not only reduce the strength to the desired limit of 3 per cent. of phenol or its homologues but they could prevent damage to clothes and other articles. It seems to us that all disinfectant preparations should be required by law to conform to a definite antiseptic value.

SUICIDES IN PUBLIC ASYLUMS FOR THE INSANE.

IN the *Journal of Mental Science* for July Dr. H. A. Benham, medical superintendent of the Fishponds Asylum, Bristol, gives an account of his studies of suicides which had occurred during the period 1890 to 1902 in the public asylums of England and Wales. During that period 201 cases of suicide occurred, 126 being males and 75 females. 16 patients committed suicide after effecting their escape and 20 patients did so while out "on trial." As to the means chosen for committing the suicidal act, a little over 50 per cent. of the total number adopted the method of hanging themselves, while 13 per cent. effected the act by cutting their throats. The other methods adopted were as follows in descending order of frequency—viz., drowning, strangulation, injury by railway trains, poisoning, jumping from windows, and suffocation. Of the suicides which actually occurred within the precincts of asylums the act was committed during the day in 79 per cent. of cases and by night in 21 per cent. "Taking the suicides committed by night," says Dr. Benham, "the smaller number is probably accounted for by the fact that not only is a smaller number of hours in question (some of which are passed in sleep) but also that all the suicidal patients are at that time concentrated in observation dormitories." On no pretence is any suicidal patient allowed at *the present day to take anything to bed.* Neglect of this precaution had in the past led to many suicides, the means adopted by the would-be suicides varying from a secreted handkerchief for tying round, or stuffing into, the throat to a piece of sharpened iron or tin for cutting the throat. All suicidal patients now sleep in special wards, each of which is specially "staffed." Sharp instruments, such as knives, razors, and scissors, are locked up and are never allowed to come within reach of suicidal patients, all medicines are kept locked up in cupboards in each ward, and the doses prescribed for sick patients are only given out by the charge attendant or his deputy. Nurses in special charge of suicidal patients or while present in the wards are not permitted to wear hat-pins, the uniform cap being fastened with a safety-pin. Finally, the vigilance of the night attendants is tested by a system of electric clocks connected by wire with a recording apparatus which is placed in the medical superintendent's office. In the dormitories the clock is "pegged" every half hour—thus guaranteeing that the attendants are awake—and a record of each "pegging" is automatically registered in the medical superintendent's office. The rooms of attendants are kept locked so that patients cannot *obtain any articles from them. In short, the whole system* of supervision and care of suicidal patients has been, says Dr. Benham, so highly perfected in asylums that suicides are now very rare events even in our largest public asylums.

Sir William Selby Church, the President of the Royal College of Physicians of London, will deliver the opening lecture of the winter session at the Post-graduate College, West London Hospital, Hammersmith-road, W., early in October.

THE King has approved of the re-appointment of Mr. William Gabriel Rockwood, M.D. Madras, as an unofficial member of the Legislative Council of the Island of Ceylon.

THE ILLNESS AND DEATH OF THE POPE.

(FROM A CORRESPONDENT.)

THE following detailed story of the illness and death of the Pope has been sent to us by a thoroughly well-informed correspondent. The complete accuracy of the public bulletins is supported by his statements:—

On Tuesday, June 30th, the Pope complained of slight feelings of dyspepsia and as he was particularly fond of physicking himself he determined to take a dose of castor oil. This acted rather too strongly during the next two days, but he went on with his usual receptions and with his drives in the gardens of the Vatican, which he had begun rather earlier than usual this year. On Friday, July 3rd, during the afternoon drive, he did not feel at all well and returning to his apartments went to bed where he fell into a prolonged fainting fit. Dr. Lapponi, who has been the Pope's private physician for many years, on being summoned, declared that this was due to the excessive action of the castor oil which had brought on some disturbance of the stomach and, in fact, the Pope would not take any nourishment at all, refusing even a glass of claret which was his usual "pick-me-up." Some anxiety was felt during the night which was apparently passed by the Pope in a state of semi-delirium until the dawn, in spite of a dose of sulphonal (his usual soporific), when after taking a little cordial he felt re-invigorated and calmer.

During the next day, Saturday, the loss of appetite continued and in addition the Pope suffered from shortness of breath, so that the daily receptions had to be postponed. There was, however, no fever. Towards evening *symptoms* of prostration made their appearance, the pulse being very weak and the action of the heart being barely perceptible. A hypodermic injection of caffeine was given which caused a great deal of pain. Caffeine was also given by the mouth, as was also some nourishment, and a little sleep was obtained. Dr. Lapponi slept in the Vatican. A consultation with Professor Mazzoni was determined on and this took place on the next morning, Sunday, July 5th, at 8.30. The bulletin then issued was as follows:—

> Dr. Lapponi, being anxious concerning the health of the Holy Father, held this morning a consultation with Professor Mazzoni, who confirmed the diagnosis already made by his colleague of "senile [illegible] proved of the treatment instituted. [illegible] tient is, considering his age, serious [illegible]

Professor Mazzoni, it may be remembered, operated on the Pope three years ago for a suppurating cyst in the side with excellent results.[1] He is surgeon to the ancient hospital for women of San Giovanni in Laterano and is a *privat-docent* for gynæcology in the university.

I had an interview with Professor Mazzoni in the evening. He stated that the hepatisation affected the upper and middle lobes of the right lung and that there had been symptoms of considerable cardiac weakness and some difficulty in respiration; there was no fever, cough, or expectoration. At 9 P.M. on Sunday the following bulletin was issued:—

> Since the morning there has been slight increase in the weakness. The objective conditions of the thorax remain unaltered. Respiration somewhat frequent. Pulse weak, but not irregular. Temperature subnormal. Mind most clear.

Notwithstanding his weakness the Pope remained out of bed for a part of the day, dictating letters and making his final dispositions on temporal and spiritual matters. He also dictated some Latin hexameters (and requested his secretary to send them immediately to be printed, as he wished to see the proofs). The first line of these runs:—

"Sol moritur vespri cedens sua regna rubenti."

They are somewhat melancholy and comprise a farewell to all Christians.

Shortly after this consultation the Viaticum, or Last Sacrament, was administered to the Pope sitting up in his bed in the presence of several cardinals and other members of his family and intimates. During the recitation of the Confession when the words "*Mea culpa, mea culpa, mea maxima culpa*" were reached the Pope extended his hands and struck his breast three times in token of deep sorrow for the sins of his life. Then with astonishing mental clearness he requested the cardinals present, numbering 28 or 29 in all, to approach one by one. He recognised them individually and had a parting word for each. The bulletin issued on Monday morning was as follows:—

> [illegible] condition of the august sufferer, while no better, is certainly no worse.

It was stated, but not officially, that caffeine was also given by the mouth during the night. The nourishment consisted of strong soup, eggs, and various stimulants. The bulletin in the evening was as follows:—

> 8 P.M.—This evening the symptoms of general depression are accentuated. Respiration more frequent and superficial. Pulse small, and sometimes imperceptible. Temperature subnormal. Intellectual faculties unimpaired.

After the publication of this bulletin Extreme Unction was administered.

On Tuesday, the 7th, the morning bulletin was as follows:—

> 10 A.M.—A sleepless and agitated night, but nourishment was better taken. General condition somewhat better. A change noticed in the [illegible] is a depression of the cardiac function, which has caused a delayed renal function, and cyanosis in the distal phalanges of the fingers and toes.

The treatment relied upon was the administration of digitalis, camphor, and expectorants by the mouth, and stimulating applications to the skin. Baccelli's symptom consists practically in the old succussio Hippocratis, with this exception—that the patient himself causes the splash of the effused fluid by repeating aloud the words "trenta tre," and it is not to be confused with the other symptom of Baccelli which consists in distinguishing between a serous and a purulent effusion into the pleura by means of the differences heard in auscultation of a whisper in these two conditions.

---

[1] THE LANCET, March 11th, 1899, p. 731.

The operation of paracentesis was performed a little before 1 P.M. After a preliminary cocainisation an exploratory puncture was made in the seventh interspace and the presence of a sero-sanguinolent effusion was ascertained. The needle of the Pravaz syringe was withdrawn and that of a Potain's aspirator was inserted and between 700 and 800 grammes of fluid were withdrawn in 20 minutes. A collodion dressing was then applied. The Pope was much pleased at the painlessness of the operation and complimented Professor Mazzoni, saying that he felt much relieved by it. At 2 P.M. the following bulletin was issued :—

> The exploratory puncture gave sero sanguineous liquid. Thoracocentesis was next performed, withdrawing about 800 grammes of liquid. After the withdrawal a rapid examination revealed mucous râles in the region of the lung first affected. His Holiness supported the operation very well, his *morale* has been improved by it, and the general condition seems better. He is now reposing.

On the same evening at 8.30 the following bulletin was issued :—

> The condition continues to be fairly satisfactory, as mentioned in the last bulletin. The functions of the heart and of respiration continue to improve slowly but gradually.

On Wednesday, the 8th, the following bulletin was issued at 10 A.M. after a consultation lasting one and a half hours :—

> The night was passed fairly tranquilly though without refreshing sleep. The pulse is frequent but regular, the respiration not so free as yesterday. The condition of the Holy Father does not permit of a long examination but permits of the statement that the pulmonary process is tending to resolution and that the pleural effusion is not being again poured out. The condition of the august patient, however, is not a tranquil one on account of the state of depression, which is increasing. During the night there seems to have been some difficulty in passing the urine, which depressed the Pope very much.

At 7.30 P.M. the following bulletin was issued :—

> The day has been passed tranquilly without attacks of weakness Pulse less frequent, regular, and a little more sustained. Respiration easy. The general condition is better.

Nourishment was taken several times during the day and consisted of meat grated in soup and some spoonfuls of claret, but hardly enough was taken.

On Thursday, the 9th, the following bulletin was issued at 9.35 A.M. :—

> The night has been a tranquil one and the august patient has reposed. The pneumonic process is in a state of complete resolution in that part of the lung which is not covered by the small quantity of fluids still remaining in the pleural cavity. The general condition continues to be better.

It was also stated, but not officially, that the cyanosis of the fingers was less and that the lips were of a better colour. The temperature ranged between 36·2° and 36 6° C. According to *La Tribuna*, the official organ, Dr. Guido Baccelli, the Minister of Agriculture in the present Cabinet, who is also professor of medicine in the University of Rome, stated to-day that he "was glad that his studies had been able to contribute to the diagnosis and treatment of the illustrious patient." This refers to the fact that he was the first to suggest the existence of fluid in the pleural cavity.

At the consultation held on the morning of the 9th it was decided to call in at the evening consultation as a physician consultant, Dr. Rossoni, the professor of special demonstrative medical pathology (performing functions almost exactly corresponding to those of a medical registrar), who also takes over the work of Professor Baccelli when his Cabinet duties do not permit him to do it. The Pope, when he was told of this by Dr. Lapponi, said that he was perfectly satisfied with his two medical attendants and asked why he should have a third. Dr. Lapponi explained that he thought it would increase the authoritativeness of the bulletins. The Pope answered that he did not insist and was grateful for their kindly thought. After the consultation was over the Pope became worse and it was decided to hold another consultation at 4.30 P.M. When Professor Rossoni was introduced the Pope, ascertaining that he was a Roman, asked him if he had studied under De Matteis, who had a ward in the Hospital of Santo Spirito and was the foremost exponent of the Roman school of medicine in his happy boyhood which he remembered so well. As this was about the year 1824 Professor Rossoni naturally replied that he did not remember him. The consultation lasted about an hour and after it, at 6 P.M., the following bulletin was issued :—

> The general condition of the august patient becoming somewhat worse during the day a consultation was h [illegible] there was also present Professor Rossoni. An [illegible] made and it was ascertained that the pleural [illegible] increasing. The sounds of the heart are weak, without symptoms of valvular lesions. Pulse easily compressible, 90. Respiration superficial, infrequent. Diuresis scanty. The condition of His Holiness may be considered as serious.

After the consultation the Pope asked one of his medical attendants : "Do you hope more or fear more?" showing his complete knowledge of his precarious condition.

Dr. Lapponi and Professor Mazzoni visited the Pope again at 10 55 P.M. and found that the general condition was unaltered. During the visit the Pope asked them what Professor Rossoni had said and asked to see the bulletin. To this quite unexpected question the answer was given that the bulletin was only issued in the morning and that it would then be laid before him. This has necessitated the printing of a special bulletin "ad usum Ponteficis."

On Friday, the 10th, when Professor Mazzoni and Professor Rossoni entered the room at 10 A.M. the Pope, who was sitting up, offered the latter his snuff-box and said that he did not feel quite so well, complaining in particular of a heavy feeling at the pit of the stomach. This, it is to be noticed, the Pope had also complained of just before the first operation. He then went back to bed again without any help and the operation was performed after a preliminary hypodermic injection of camphorated oil and hypodermic cocainisation. About 1000 grammes of a sero-sanguinolent fluid were withdrawn in the time of 20 minutes and on hearing the fluid being poured out of the aspirator into another receptacle the Pope said : "What a fountain." A microscopical examination of the fluid was rapidly made and there were found in it "many mononucleated corpuscles, a few multinuclear, many hæmatocytes. The presence of tubercle and of a thoracic tumour was thus to be definitely excluded." At 11 A.M. the following bulletin was issued :—

> The august patient passed the first half of the night with a certain amount of tranquillity but afterwards the difficulty of respiration and malaise increased and there was a greater sense of oppression. Pulse small, weak, 92. Complete apyrexia. Scanty diuresis. An increase of the endopleuritic effusion having been ascertained the indication for emptying is definite. A thoracocentesis was immediately performed by Professor Mazzoni. About 1000 grammes of sero sanguineous fluid were extracted. His Holiness supported very well this, the second, operation. After the operation the respiration and the strength of the heart suddenly improved.

At 9 P.M. the following bulletin was issued :—

> His Holiness has reposed during the day without pain. The pulse [illegible] ie strength of this morning after the [illegible] Respiration, 28; temperature, 36·4° C. [illegible] General condition unchanged.

On Saturday, the 11th, the bulletin was as follows :—

> During the night His Holiness has reposed at intervals. Pulse 90, its strength and compressibility being unchanged from last night. Respiration, 30; temperature, 36° C. Renal function always deficient. General condition somewhat better.

At 8 P M. the bulletin was as follows :—

> The day has been passed fairly tranquilly. The improvement in the general condition has permitted of the repetition of the physical examination of the thorax. The level of the slight amount of fluid remaining from the withdrawal (of fluid) performed yesterday has remained stationary. In the region above this level faint pleuritic friction sounds and a few mucous râles can be heard. Pulse less small and less weak. Pulsations, 86; respiration, 28; temperature, 36 9° C. The *morale* of the august patient is better.

The following bulletin was issued on Sunday, the 12th, at 9 A.M. :—

> The night has been passed tranquilly and several hours of sleep have improved the general condition of His Holiness. Pulse less small and a little stronger; pulsations, 82; respirations, 30.

The evening bulletin was as follows :—

> Nothing noteworthy in the course of the day. The general condition of His Holiness is unchanged. Pulsations, 86; respiration, 30; temperature, 36·8° C. A good night was passed.

At this point in the illness one of the medical men in attendance considered that a critical period might have arrived though the hope was necessarily very slender. But two days later the increasing weakness became manifest and for the next four days the bulletins bore but one construction —the strength of the patient was slowly failing. The pleuritic fluid, as it collected, was withdrawn by a Pravaz syringe, otherwise medical care was chiefly directed to the administration of nourishment. On Sunday, July 19th, the Pope fell into a condition of stupor, the long death agony being closed on July 20th. A few hours before his death he recovered consciousness and twice raised his hand in the act of bestowing the blessing.

The Pope was nursed throughout by his faithful valet, Pio Centra, and by Dr. Lapponi. While the windows of his room have only been opened for an occasional ten minutes in ie early morning, oxygen has been continually generated in ie next room in order to keep the atmosphere purer, tiated as it necessarily has been by the presence of many eople—cardinals, members of the Pope's family, and other itimates.

THE

ONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

(FROM A SPECIAL CORRESPONDENT.)

THE annual meeting of the Royal Institute of Public ealth was held at Liverpool from July 15th to 21st, under ie Presidency of the Earl of DERBY.

Those splendid municipal buildings, the St. George's Hall id the Walker Art Gallery, are admirably adapted for the irposes of a congress and were generously placed at the isposal of the institute by the corporation. The sectional [illegible] e near at the University College [illegible] adapted to the purpose. Some [illegible] Congress and inspected with great iterest the various municipal enterprises of Liverpool, such s the model dwellings, the sewage and water works, the ust destructors, and all the numerous undertakings which iark the great city as a thoroughly advanced and liberal-iinded place. Many neighbouring factories and works, uch as, in particular, Messrs. Lever's model village, were pen to view and the facilities so afforded were largely made se of. Warm praise must be accorded to Dr. E. W. Hope, he energetic medical officer of health of Liverpool, and the onorary general secretary of the Congress, for the admirable rrangements that were made for the instruction and entertainment of so numerous a company. Excursions to Chester nd Eaton Hall, Hawarden Castle, Northwich, and other laces of interest were arranged and well patronised, although he wet weather rather marred the general enjoyment.

THE OPENING MEETING.

The opening meeting was held on Wednesday evening, uly 15th, in St. George's Hall. Lord DERBY in his inugural address said that sanitation and the promotion of ealth were in the mouth of everyone, but he was not sure hey were not priding themselves too much upon the dvances they had made. He was not sure that on sanitary uestions after all they were so much in advance of some ations of antiquity and instanced as examples the Mosaic egulations of camp sanitary administration and the queducts and drainage systems of the Romans. As egards personal cleanliness some of the nations of the ast in many respects could hardly be surpassed. That isects might convey malaria appeared to have occurred o a Roman writer on agriculture Contrary to the general pinion, contrary to statistics, he doubted the halo of ealthiness thrown over the country as opposed to the towns. No doubt country life appeared to be ideal, but certainly n times gone by life in the best cottages was infinitely nferior to anything in the worst slums of the towns now. n conclusion, he remarked that science must progress hrough an interchange of ideas and by such congresses as he present one rays of light would surely be thrown where larkness had hitherto reigned. The Harben medals for 1901 ind 1902 were then conferred upon Sir Charles Cameron, C.B., and Dr. W. R. Smith, the President of the institute.

The meeting of sections commenced on July 16th.

I.—SECTION OF SANITARY ADMINISTRATION.

Sanitation of Congested Areas and Rehousing the Dispossessed.

Mr. TAYLOR, M.P., the President, in his opening address said that the housing question was one of the most important that the section, or, indeed, the whole Congress, had to deal with. The degree of congestion in cities varied and no longer should money be allowed to be wasted in curing [illegible] ounding belt [illegible] He would [illegible] a three mile limit outside their boundary. The first duty of a municipality was not to the artisan, but to the poorest poor who were ejected in the general interest.

Dr. JAMES NIVEN, medical officer of health of Manchester, read a paper on Rehousing the Poor on the Outskirts of Large Cities. He said it was generally recognised that an effort should be made by sanitary authorities to house as many as possible of the poorer working classes on the outlying parts of their districts under improved conditions as regards light, air, space, and construction. A great impulse had already been given to this movement by the development of electric trams. Touching municipal undertakings, he said that the main question was, How far could the workmen live from their place of employment?

Dr. SPOTTISWOODE CAMERON, medical officer of health of Leeds, discussed the Methods of Dealing with Unhealthy Areas. He pointed out that the first part of the Act of 1890 was intended specially for those cases where a very large area involved so much slum property that a general reconstruction of the district was necessary, while the second part dealt (1) with individual houses which were insanitary, (2) individual houses which were obstructive, and (3) smaller areas somewhat of the character of those in the first part. In many cases, he said, the removal of an obstructive building would let in air and light into an insanitary district, often with great advantage. Obstructive buildings were of two classes—(a) those which were used for habitation and were unfit; and (b) those which were either not used for habitation or were themselves fit for such use. The dealing with such obstructive buildings might be initiated by the medical officer of health on his own accou [illegible] householders of the district. Tl [illegible] are a report to the authority as [illegible] building and the cost of pulling it down and acquiring the land. This report it must ask for and must consider when made along with the representation. If it decides to act, copies of both are sent to the owner of the land, giving him an opportunity of stating his objections, after which the authority decides whether the building shall be pulled down. He then proceeded to give examples of the method of procedure.

Dr. R. S. MARSDEN, medical officer of health of Birkenhead [illegible] far outside [illegible] there in free [illegible] actice on account [illegible] l of over- [illegible] owners to make the houses [illegible] cy. A certain class, those [illegible] amounting, perhaps, to a [illegible] not be so dealt with; for [illegible] municipal lodging-houses. He referred to the admirable dwellings of this class designed by Mr. Turton of Liverpool.

Mrs. Councillor DOCKRELL of Blackrock said that she approached the question from the woman's point of view. Tenement houses were detrimental to family life and conducive to quarrels. It was an unfortunate fact that dispossessed persons rarely went into the new houses.

A joint meeting of the Congested Areas and Municipal Hygiene Sections considered the question of water-supply and a paper was contributed by Mr. PARRY, the Liverpool water engineer.

A Garden Village.

An object-lesson in connexion with the Congested Areas Section was given by the visit to Port Sunlight, by kind invitation of Messrs. Lever Brothers. This is a delightful "garden" village, the cottages of which are constructed in a charming and artistic style. Mr. Lever, who conducted the members, said that the village was no wonder at all. The whole question was the number of houses per acre. He thought that the maximum should be ten; if they got 20 the death-rate went up, and so on until they came to 50, when it became a congested area.

II.—SECTION OF PREVENTIVE MEDICINE AND VITAL STATISTICS.

The President of this section was Dr. SPOTTISWOODE CAMERON who in his opening address remarked upon the growing importance of preventive medicine. It was being realised that systematic inspection was far more effectual than waiting for complaints.

The Prevention of Consumption in a Large City.

Dr. NATHAN RAW, physician to the Liverpool Sanatorium for Consumptives, contributed a paper on the above subject. He pointed out that 2000 people died every year in Liverpool from tuberculosis and said that there were at present between 5000 and 6000 consumptives in the city. He pointed out that the disease was infectious, but only when ordinary sanitary and personal precautions were not observed, and urged that the patient in an advanced stage ought to be separated from other members of the family or removed to some suitable institution. In his opinion consumption was frequently conveyed to children by milk from tuberculous cows. He suggested, as far as Liverpool was concerned, that it would be necessary to appoint a tuberculosis committee under the control of the health department, working in conjunction with the general practitioners and charity organisations in the city. The institutions necessary to carry out this plan would be: (1) a centrally located office at which all consumptives might seek advice and where inquiries might be made by the committee; (2) a municipal sanatorium in some healthy district near Liverpool where the early cases might be treated, the patient to pay according to his means; and (3) a reception hospital for at least 100 incurable patients who could be removed from their surroundings and would no longer act as the most potent agents in distributing the disease. He thought that if a consumption colony could be established in some healthy locality near Liverpool where all poor and needy consumptives could be placed it would do more than anything else to stamp out this disease from the city.

This paper led to an interesting discussion.

Dr. W. G. WILLOUGHBY (Eastbourne) thought that the value of sanatoriums had been over-estimated.

Dr. HOPE disagreed with the last view and considered that compulsory notification could not at present be asked for.

Dr. SMITH (King's College, London) said that compulsory notification began at the wrong end. As regards sanatoriums, considering the number of consumptives the authorities were practically asked to build hospitals for incurables.

Sir CHARLES CAMERON (Dublin) was not convinced that compulsory notification was undesirable. Notification should not be compulsory, however, until it had definitely been decided by bacteriological examination that the case was one of tuberculosis.

Dr. W. J. R. SIMPSON (King's College, London), while doubtful as to the value of hospital treatment, thought highly of the suggestion of establishing colonies. Compulsory notification was the beginning of a serious attempt to grapple with this great national evil.

Dr. RAW, in his reply, said that from the scientific point of view there could be no doubt as to the advisability of compulsory notification, but since 200,000 poor working people suffered from consumption in this country such a course would dislocate a vast amount of domestic life. The disease ought to be put into a category by itself, isolation being needed only in the case of those incurable patients who could not in any way isolate themselves.

Underground Bakehouses.

Dr. T. W. N. BARLOW, medical officer of health of Bootle, read a paper upon the Requirements in regard to Underground Bakehouses. He remarked upon the difficulty in dealing with underground bakehouses and considered that medical officers of health should recommend standard regulations with regard to construction and lighting which might be modified in particular instances.

The Transmissibility of Infectious Diseases during the Incubation Period.

Dr. H. S. WILLSON (King's College, London) read a paper upon this subject. He said that in the vast majority of instances infectious diseases were not transmissible until the actual onset of symptoms, and this view was sufficient as a rule for practical purposes. But the rare exceptions were at least of scientific interest and might be important for preventive medicine. Opinions from various text-books and a few cases were quoted. The speaker then brought forward some bacteriological considerations and showed that diphtheria was undoubtedly infectious during the incubation period. He called attention to the fact that people might harbour the Klebs-Löffler bacillus for a considerable time—many days or even weeks—and eventually develop the disease apart from any fresh infection. He then distinguished between a "potential" and "actual" incubation period in diphtheria. The one might pass into the other and the patient be capable of communicating the disease during the whole period. He also brought forward reasons for believing that typhoid fever was capable of being transmitted apart from any symptoms and during the period of incubation. His conclusion was that as far as present knowledge went those in sanitary authority might neglect the possibility of infection during the incubation period in all diseases except diphtheria and typhoid fever. He urged the importance of provision for proper bacteriological investigation in all cases of suspected diphtheria and also for "contacts," and lastly considered that in the near future the same consideration would have to be given to the early bacteriological investigation of typhoid fever.

In the discussion which followed Dr. MARSDEN brought forward his physical theory that infection was a matter of wave length.

Dr. A. JOHNSTON (Glasgow) did not believe that infection during the incubation period ever occurred.

Dr. J. T. NEECH (Halifax) and Dr. BUTLER HOGAN (Tottenham) mentioned cases of small-pox in which they concluded that infection had occurred in the incubation period.

III.—SECTION OF BACTERIOLOGY AND COMPARATIVE PATHOLOGY.

The Value of Abstract Research to Practical Sanitation.

Professor RUBERT BOYCE, F.R.S., President of the Section, took the above subject for his theme in opening the meeting. He said that in a city like Liverpool where a new university had been created no pains should be spared to make the university not only the best equipped of its kind but also that its great departments should be so organised that they could be readily used by the city corporation, by district authorities, by the Chamber of Commerce, and by commercial firms seeking advice. They wanted on their part the advances which they made in science to be used to the full advantage of the community and in return they required the active support of the community. In Liverpool this inter-dependence had been fully recognised. He pointed out the value of a bacteriological department to the health department of a great city and he said that there existed in addition to the routine checking work a whole field of research in regard to plague, cholera, rabies, purity of water, &c., in which the community was directly interested and to the support of which it was asked to contribute directly. The relationship of bacteriology to the water engineer had also had ample demonstration, for that officer had to recognise that his worst enemy was a pathogenic organism. He now thoroughly recognised the significance of the colon bacillus and it was a remarkable step forward that probably every oyster merchant also realised the importance of freeing the beds from this pest. All this tended to impress on the community the absolute necessity of supporting, and keeping in touch with, scientific progress. It was splendid to see how citizens were coming more and more to the aid of men of science and were endowing cancer and other researches.

Interesting discussions upon the bacterioscopic analysis of water, the nature of the pseudo-diphtheria (Hofmann) bacillus, and the diseases of animals communicable to man followed, and several valuable papers were contributed.

(To be continued.)

MEDICINE AND THE LAW.

The Address of the President of the Medico-Psychological Association.

IN his presidential address to the Medico-Psychological Association Dr. Ernest W. White did not confine himself to any special subject connected with the care and treatment of the insane, but preferred to review the general situation by the light of events and statistics of recent date and to discuss changes and improvements either capable of being introduced by legislation and other means, or already projected. Among innovations with regard to which definite proposals are before the Legislature, the Lunacy Acts Amendment (London) Bill, introduced by Lord Carrington in the House of Lords, is regarded by Dr. White with some disfavour, although the principle which it seeks to introduce naturally commends itself to him. The object of this Bill is, according to its memorandum, to establish in various districts in London under the control of the County Council houses at which persons alleged to be lunatics may be received for preliminary examination and treatment. There are many defects in the present system whereby persons of unsound mind find their way, after preliminary detention in workhouses and prisons, into large lunatic asylums where the nature and probable duration of their derangement cannot be so well studied with a view to their future treatment as it might be in smaller institutions maintained expressly to that end. The memorandum of the Bill observes with regard to this, "It is claimed for the system proposed that it will be not only beneficial but economical in its operation by tending to lessen the number of persons detained as lunatics in the county asylums at the public expense, while it will be useful in assisting the classification of patients and the diagnosis and cure of mental disease in its earliest stages," and no one will dissent from the view that such a system efficiently worked may some day prove of practical utility. Dr. White, however, regards the proposals of Lord Carrington's Bill as tending to the institution of new hospitals for the insane in central metropolitan districts, and referred to a special report of the County Council, published in 1890, in support of this opinion. In the Bill itself there is little to justify the anxiety he expresses with reference to this, nor with regard to the manner in which he fears that the County Council will carry out the duties which it is now willing to undertake He asks whether there is any guarantee that the superintendent, who will also be resident medical officer, of the proposed receiving houses will have been properly trained in the treatment of mental diseases in a public institution for the insane, and also whether the visiting medical staff to be appointed will have had proper experience gained in public asylums. We hope and think that the London County Council are not likely deliberately to appoint ill-qualified persons to fill important offices of this kind, so that there is no need to anticipate the reverse in an Act of Parliament. Dr. White has a proposal to meet the difficulty of obtaining assistant medical officers at county and borough asylums, where it is known that the higher posts are few in number and that promotion must in consequence be slow and uncertain. He suggests that an assistant medical officer should be able to retire, "say at the end of five years, if he so desires, with a gratuity of £500, or at the end of ten years with one of £1000," and points out that any sum so earned will aid in the purchase [illegible] will mean the [illegible] disease throug [illegible] and borough asylums can see their way to carry out such a suggestion we have no doubt that they will find an increase in the number of candidates ready to come forward for the posts in question. Young medical men gain their qualification by a long and costly course of training and are not likely to disregard positions offering marked pecuniary advantages.

Refuse as a Nuisance.

An injunction was granted by Mr. Justice Joyce on July 15th restraining the Keymer Brick and Tile Company, Limited, from using rough ashes, rubbish, or house refuse as fuel so as to occasion a nuisance to persons in the neighbourhood of their brickfields or so as to be injurious to public health. The defendants purchased what they termed rough ashes, apparently London refuse containing ashes, and brought it by rail to their works, where it was screened, the ashes and breeze being used as fuel. The accumulation of dead dogs and cats and other non-inflammable matter caused the nuisance complained of and one of the witnesses, a gentleman keeping a preparatory school close by, spoke of the numbers of flies which were bred in the decaying matter and stated that he had caught some flies for bacteriological examination, evidence as to the result of which was given. The action was brought by the Attorney-General at the instance of the Chailey rural district council. In the course of his judgment his lordship said that the question was one of fact and not of law and that with regard to the law it was only necessary to say that in law a public nuisance need not necessarily be one injurious to public health. It was enough to show that it was a substantial injury to the comfort of persons within its sphere. He had nothing to do with the question whether the defendants could properly carry on their business in the place where they did so or with the difficulty of disposing of London refuse. He saw no reason to doubt that a serious and disgusting public nuisance had been created.

Coroners and Medical Evidence.

At an inquest held recently at Southend upon the body of a man found upon the beach with his throat cut there was no medical evidence forthcoming. A juror, who felt doubts as to whether the wounds upon the deceased could have been self-inflicted, asked for a medical opinion on the subject. The coroner thereupon expressed the view that none was necessary and the jury, in order to call attention to their dissent, nearly returned a verdict of "Found drowned." Upon this, the inquest was adjourned in order that medical testimony might be obtained, and a few days later a medical man gave evidence to the effect that death was due to the wounds in the throat and that the position and nature of these were consistent with their having been self-inflicted. With regard to the calling of medical evidence at an inquest *the jury were clearly within their right in asking for it*, for a verdict in all cases should be founded on evidence and on nothing else. The jury in deciding the cause of death are not experts and their "view" of the body is not such an examination as can enable them in any way to exceed their ordinary functions. The coroner has the responsibility of guiding them and helping them properly to appreciate the evidence before them. By the twenty-first section of the Coroners Act, 1887, where medical evidence has been given and the jury are not satisfied with it, they may require the coroner to call in further medical evidence and the coroner is bound to comply with this requisition. The end of the case in question was, however, a curious one, for the jury having no evidence before them pointing conclusively, in their opinion, to suicide, still refused to return a verdict to that effect. Nor did they find that the wounds were the cause of death and leave the method of their infliction open. They appear to have refused to adopt any reasonable course and finally returned a verdict of "Found drowned."

Spreading Infection.

At Clerkenwell on July 15th a man and his wife were prosecuted by the Islington borough council for publicly exposing and placing in a cab two children suffering from diphtheria and the woman was also summoned for exposing herself when suffering from the same complaint. The female defendant had taken the children to the Great Northern Central Hospital, had been told that they were suffering from diphtheria, and had refused the offer of an ambulance to take them to an isolation hospital. The hospital authorities appear to have informed the medical officer of health of the district where they resided, and he having traced them found that the family, including three healthy children and a grandmother, had gone by cab and train to Liverpool-street station where they were waiting on the platform for a train. Here, while the sanitary inspector was absent with the father, the woman and children managed to get into a train and started on their journey. After the railway authorities had had the train stopped the patients were detained at Maldon until they were well. Fines amounting to £5 4s. were imposed. The sanitary authority and the hospital are to be congratulated on their energetic and effective action in this case. It will be observed that the defendants, though able to afford cab and railway fares, were not above seeking medical advice from a hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8677 births and 3894 deaths were registered during the week ending July 18th. The annual rate of mortality in these towns, which had been 14·3, 14·4, and 13·7 per 1000 in the three preceding weeks, further declined last week to 13·5 per 1000. In London the death-rate was 13·0 per 1000, while in the 75 other large towns it averaged 13·7 per 1000. The lowest death-rates in these towns were 5·4 in Bury, 6·3 in Hastings and in West Bromwich, 6·4 in Norwich, 6·6 in Aston Manor, 7·2 in Handsworth, 7·3 in Hornsey, and 7·4 in Croydon and in Willesden; the highest rates were 18·9 in Warrington and in Burnley, 19·1 in Rotherham, 20·1 in Great Yarmouth, 20 6 in Bootle, 20 9 in Rochdale, 21·4 in Middlesbrough, and 22·6 in Wigan. The 3894 deaths in these towns last week included 473 which were referred to the principal infectious diseases, against 429, 436, and 441 in the three preceding weeks; of these 473 deaths 170 resulted from diarrhœa, 95 from measles, 86 from whooping-cough, 49 from diphtheria, 36 from "fever" (principally enteric), 31 from scarlet fever, and six from small-pox. No death from any of these diseases was registered in Hornsey, Hastings, Bournemouth, Southampton, Reading, Burton-on-Trent, Wolverhampton, West Bromwich, Smethwick, Grimsby, West Hartlepool, Cardiff, or Swansea; while the highest death-rates from the principal infectious diseases were recorded in Coventry, Stockport, Birkenhead, Bootle, Wigan, Burnley, Sheffield, Rotherham, and Middlesbrough. The greatest proportional mortality from measles occurred in Ipswich, Coventry, Nottingham, Wigan, Sheffield, Middlesbrough, and Merthyr Tydfil; from scarlet fever in Bootle; from diphtheria in Great Yarmouth; from whooping-cough in Walthamstow, Oldham, and Sheffield; and from diarrhœa in Walsall, Wallasey, Birkenhead, Liverpool, Bootle, Wigan, Bolton, Burnley, Leeds, and Rotherham. The mortality from "fever" showed no marked excess in any of the large towns. Of the six fatal cases of small-pox registered in these towns last week three belonged to Liverpool, two to Gateshead, and one to Manchester. The Metropolitan Asylums hospitals contained 71 small-pox patients on Saturday last, July 18th, against 67, 57, and 77 on the three preceding Saturdays; seven new cases were admitted during last week, against seven, four, and 31 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 1644, 1646, and 1700 at the end of the three preceding weeks, had further risen to 1710 at the end of last week; 243 new cases were admitted during the week, against 234, 241, and 253 in the three preceding weeks. The deaths referred to the diseases of the respiratory organs in London, which had been 150, 164, and 127 in the three preceding weeks, further declined last week to 115, and were 44 below the number in the corresponding period of last year. The causes of 36, or 0·9 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Leeds, Gateshead, Newcastle-on-Tyne, and in 52 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Salford, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19·1, 16·3, and 16·2 per 1000 in the three preceding weeks, further declined to 15·2 per 1000 during the week ending July 18th, but was 1·7 per 1000 above the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·3 in Aberdeen and 12·4 in Perth, to 17·6 in Dundee and 18·9 in Paisley. The 497 deaths in these towns included 22 which were referred to diarrhœa, 15 to whooping-cough, 11 to measles, four to diphtheria, three to "fever," and two to scarlet fever, but not one to small-pox. In all, 57 deaths resulted from these principal infectious diseases last week, against 65, 58, and 82 in the three preceding weeks. These 57 deaths were equal to an annual rate of 1·7 per 1000, which was slightly above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 16, 17, and 31 in the three preceding weeks, declined again last week to 22, of which 15 occurred in Glasgow, three in Dundee, and two in Edinburgh. The deaths from whooping-cough, which had been 18 in each of the two preceding weeks, declined to 15 last week, and included six in Glasgow, three in Edinburgh, two in Paisley, and two in Greenock. The fatal cases of measles, which had been 13, six, and 13 in the three preceding weeks, decreased again last week to 11, of which six were registered in Glasgow, three in Edinburgh, and two in Paisley. The four deaths from diphtheria corresponded with the number in each of the three preceding weeks, and included three in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 92, 86, and 90 in the three preceding weeks, declined again last week to 73 but were nine in excess of the number in the corresponding period of last year. The causes of 18, or nearly 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·3, 17·2, and 18·2 per 1000 in the three preceding weeks, declined again to 16·0 per 1000 during the week ending July 18th. During the past four weeks the death-rate has averaged 18·4 per 1000, the rates during the same period being 13·4 in London and 16·4 in Edinburgh. The 116 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 16 from the number in the preceding week and included six which were referred to the principal infectious diseases, against 13, five, and two in the three preceding weeks; of these, two resulted from scarlet fever and one each from small-pox, diphtheria, whooping-cough, and diarrhœa, but not one from either measles or "fever." These six deaths were equal to an annual rate of 0·8 per 1000, the death-rates last week from the principal infectious diseases being 1·5 in London and 1·6 in Edinburgh. The 116 deaths in Dublin last week included 24 of children under one year of age and 29 of persons aged 60 years and upwards; the deaths of infants were considerably in excess of the number recorded in the preceding week, while those of elderly persons showed a slight decline. Four inquest cases and three deaths from violence were registered and 53, or nearly one-half, of the deaths occurred in public institutions. The causes of nine, or nearly 8 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JUNE, 1903.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·0 per 1000 of the population, estimated at 4,613,812 persons in the middle of the year. In the three preceding months the rates had been 5·9, 5·4, and 6·0 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, Hammersmith, Hampstead, Stoke Newington, and Lambeth; while they showed the largest excess in Fulham, St. Marylebone, Hackney, Finsbury, and Deptford. The prevalence of small-pox during June was slightly greater than that recorded in the preceding month; of the 68 cases notified during the month, 29 belonged to Lambeth, seven to Poplar, five to Wandsworth, four to Stepney, three to St. Pancras, and three to Battersea. The Metropolitan Asylums hospitals contained 57 small-pox patients at the end of last month, against 13, 47, and 60 at the end of the three preceding months; the weekly admissions averaged 12, against three, 12, and 13 in the three preceding months. The prevalence of scarlet fever showed a slight decline last month; among the various metropolitan boroughs this disease was proportionally most prevalent in St. Marylebone, Hackney, Finsbury, the City of London, Deptford, and Woolwich. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1704, 1685, and 1738 at the end of the three preceding months, had further declined to 1614 at the end of last month; the weekly admissions averaged 195, against 208, 201, and 226 in the three preceding months. The prevalence of diphtheria showed no appreciable variation from that recorded in the preceding month; this disease was proportionally most prevalent in Fulham, St. Pancras, Hackney, Finsbury, and Deptford. There were 781 cases of diphtheria under treatment in the Metropolitan Asylums hospitals at the end of last month, against 903, 760, and 808 at the end of the three preceding months; the weekly admissions averaged 99, against 126, 105, and 120 in the three preceding months. The prevalence of enteric fever showed a continued increase last month; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Fulham, Hackney, Holborn, Poplar, Deptford, and Lewisham. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 92, 53, and 51 at the end of the three preceding months, had risen again to 88 at the end of last month; the weekly admissions averaged 17, against 15, 5, and 10 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, St. Pancras, Hackney, Holborn, Stepney, and Bermondsey. The 27 cases of puerperal fever notified during the month included four in Fulham, three in Wandsworth, three in Greenwich, and two each in Islington, Stepney, Bermondsey, Deptford, and Lewisham.

The mortality statistics in the table relate to the deaths

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JUNE, 1903.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS	Estimated population in the middle of 1903.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small pox.	Scarlet fever	Diphtheria *	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

* Including membranous croup

of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending July 4th the deaths of 5705 persons belonging to London were registered, equal to an annual rate of 12·9 per 1000, against 15·9, 15·8, and 14·2 per 1000 in the three preceding months. The lowest death-rates in London last month were 6·5 in Hampstead, 8·5 in the City of London, 9·9 in Greenwich, 10·0 in Paddington and in Wandsworth, 10·3 in Lewisham, and 10·4 in Stoke Newington; the highest death-rates were 14·7 in St. Pancras, 14·8 in Stepney, 16·6 in Bethnal Green, 17·3 in Finsbury, 17·8 in Bermondsey, and 18·6 in Holborn. The 5705 deaths from all causes included 599 which were referred to the principal infectious diseases; of these, one resulted from small-pox, 244 from measles, 26 from scarlet fever, 59 from diphtheria, 138 from whooping-cough, 12 from enteric fever, and 119 from diarrhœa, but not one from typhus or from simple continued fever. The lowest death-rates last month from these infectious diseases were recorded in Kensington, Chelsea, City of Westminster, Hampstead, the City of London, Lambeth, Greenwich, and Woolwich; and the highest rates in St. Pancras, Hackney, Holborn, Finsbury, Shoreditch, Poplar, and Deptford. The fatal case of small-pox belonged to Lambeth. The 244 deaths from measles were 84 below the corrected average; among the various metropolitan boroughs this disease was proportionally most fatal in St. Pancras, Islington, Hackney, Finsbury, Shoreditch, and Bethnal Green. The 26 fatal cases of scarlet fever showed a decline of 50 from the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in Kensington, City of Westminster, Southwark, Battersea, Deptford, and Lewisham. The 59 deaths from diphtheria were 106 below the corrected average number; among the various metropolitan boroughs the greatest proportional mortality from this disease was recorded in Kensington, Hackney, Poplar, Deptford, and Greenwich. The 138 fatal cases of whooping-cough showed a decline of 60 from the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Chelsea, Finsbury, Bermondsey, Battersea, Camberwell, and Deptford. The 12 deaths referred to enteric fever were only one-third of the corrected average number; of these 12 deaths, four belonged to Hackney, two to Poplar, two to Southwark, and one each to Kensington, Hammersmith, Hampstead, and Stoke Newington. The 119 fatal cases of diarrhœa were 42 below the average number in the corresponding periods of the ten preceding years; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Hammersmith, Fulham, Holborn, Finsbury, Poplar, Bermondsey, and Deptford. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was more than 39 per cent. below the average.

Infant mortality in London during June, measured by the proportion of deaths among infants under one year of age to registered births, was equal to 91 per 1000. The lowest rates of infant mortality were recorded in Kensington, Hampstead, Stoke Newington, the City of London, Wandsworth, and Woolwich, and the highest rates in Hammersmith, Chelsea, Islington, Shoreditch, Poplar, Bermondsey, Battersea, and Camberwell.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon R. H. Nicholson to the *Albion*. Staff Surgeon F. H. A. Clayton to the *Cressy*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant F. L. Henderson, from the Seconded List, to be Lieutenant. Dated July 7th, 1903. Lieutenant-Colonel H. J. Barnes is placed on temporary half-pay on account of ill-health. Dated July 18th, 1903.

Lieutenant-Colonel F. J. Jencken is appointed to the medical charge of the Detention Hospital at Longmoor, Woolmer Forest. Major H. P. G. Elkington is appointed Chief Sanitary Officer at Aldershot. Major R. Caldwell joins at Aldershot and is appointed to the Connaught Hospital for duty.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotion made by the Government of India:—*Bengal Establishment:* To be Colonel: Lieutenant-Colonel Samuel Browne, C.I.E. Dated April 10th, 1903. The King has also approved of the retirement from the service of the undermentioned officers:—Colonel Arthur Mudge Branfoot, C.I.E., Madras Establishment (dated May 19th, 1903); Colonel William Edward Johnson, Madras Establishment (dated June 30th, 1903); Lieutenant-Colonel Denis Peter Macdonald, Bengal Establishment (dated July 6th, 1903); Lieutenant-Colonel Albert William Denis Leahy, Bengal Establishment (dated June 5th, 1903); and Major William Grant Thorold, Bengal Establishment (dated April 15th, 1903).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Lieutenant E. U. Bartholomew to be Captain. Dated June 18th, 1903.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers):—3rd Lancashire: Alan Young Greenwood to be Surgeon-Lieutenant. Dated July 18th, 1903.

Rifle: 1st Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment): Thomas Sprot Allan to be Surgeon-Lieutenant. Dated July 18th, 1903. 21st Middlesex: Surgeon-Captain E. Jones resigns his commission. Dated July 18th, 1903. 3rd London: Surgeon-Lieutenant G. W. O'F. Clark to be Surgeon-Captain. Dated July 18th, 1903.

THE COMMEMORATION OF THE KING'S BIRTHDAY.

The editor of the *Household Brigade Magazine* is entitled to great credit for the special number[1] which has been issued in commemoration of the birthday of King Edward VII. This journal is ordinarily published for the benefit of the non-commissioned officers and men of the Household Brigade, but the special number appeals not only to the army but to every loyal subject of the King. It consists of some 80 pages of letterpress and illustrations bound in an artistic cover and contains as a supplement a very good reproduction of an autograph portrait of His Majesty. Among other illustrations will be found reproductions of portraits of Prince Edward of Saxe-Weimar, Lord Chelmsford, Lord Wolseley, the Duke of Cambridge, the Duke of Connaught, and Lord Roberts, each of which is accompanied by a letter and autograph. Sir Henry Irving, of whom there is also a portrait, writes an appreciative article on "Mr. Atkins and the Stage," but the eminent actor finds that military discipline occasionally conflicts with the conditions of the drama, for the soldier on the stage never looks surprised, and "when the principal actors are in a scene of great emotion it is a little disconcerting to be surrounded by impassive faces which seem to say to the audience 'Don't mind 'em, they often take on like this, but we're used to it.'" "Our Kings at the age of Sixty-one," "The Cemeteries of the English Guards at Bayonne," "Football in the Army," "Boxing in the Army," and "Soldiers who Race," are some of the titles of the other articles. Of special interest to medical readers is the article on the Army Medical Service from a Civilian Standpoint from the pen of Dr. H. H. Tooth, C.M.G., the burden of which is that the Army Medical Service "is a highly honourable calling, offering opportunities for distinction and honours, and combining in a sense the advantages of two professions." Mr. Rudyard Kipling and Sir A. Conan Doyle both contribute autograph letters, and that excellent cartoonist "F. C. G." sends a fancy portrait of Lord Roberts in the character of St. George, Mr. Kruger as a tortoise taking the place of the dragon.

THE LATE DEBATE ON THE ARMY ESTIMATES.

The late discussion of the Army Estimates in the House of Commons was of a somewhat heated nature. Although much of it was discursive almost to irrelevancy and some of it, as might have been expected, rather abusive, Mr. Brodrick was not unequal to the occasion and some important business was done. There was little or nothing of medical interest, however, in the discussion. The War Minister took on the whole an optimistic view of things and claimed patience and fair consideration for his new Reorganisation Scheme. It would be premature, however, to proffer any opinion on this scheme until we know whether the requisite number of recruits, and of the right stamp, will be forthcoming In one important matter a compromise has been arrived at There is to be a permanent South African contingent, which will practically amount to an army corps, maintained in that country There is no doubt much to be said in favour of this measure on the score of training and military efficiency The climate is naturally a fine and healthy one, but a great deal will have to be done in the way of accommodation for the troops and sanitation, as well as sanitary administration, in order to keep them healthy and effective

---

PRINCESS LOUISE HOSPITAL, ALTON, HANTS

Princess Louise (Duchess of Argyll) accompanied by the Duke of Argyll and Lord Roberts, visited the Princess Louise Hospital at Alton, Hants, on July 16th The hospital, which was erected partly by public subscription and partly through the generosity of the proprietors of the *Daily Mail*, consists of three blocks of ten wards which are 55 feet long by 20 feet wide and contain beds for ten patients During the course of luncheon the Duke of Argyll remarked that the hospital was another instance of the intense patriotism that always pervaded the British press He thought that the patriotism of the British press might do one more thing and that was to give a prize for the best equipped ambulance and carrier for service in the field Subsequently Princess Louise presented to nurses of the hospital staff the King and Queen's medal for South Africa and Her Royal Highness was afterwards conducted over the hospital buildings by Lieutenant Colonel Rainsford, R A.M.C. Lord Roberts expressed great satisfaction with the arrangements of the hospital

GIBRALTAR · ITS SANITATION AND ITS NEW WATER-SUPPLY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

AFTER the International Congress of Hygiene and Demography held at Madrid in 1898 I was able to visit Gibraltar and I described the improvements that had then been effected. Formerly Gibraltar was anything but a healthy town The climate is not good and the sanitation was worse Thus for the 16 years terminating in 1866 the average annual death rate amounted to 29 25 per 1000 of the population, but during that year all Europe was alarmed by a serious epidemic of cholera and from that time energetic efforts have been made to deal with sanitary matters As usual, these endeavours have been rewarded by a notable decrease in the death rate, the average annual death rate for the ten years ending in 1901 amounting to only 20 65 per 1000 During the last two years, however, these conditions have not been maintained In 1901 the death rate was 22 54 per 1000 and in 1902 it reached the high figure of 23 10 per 1000 This is attributed to the exceptionally unfavourable climatic conditions, the greatest number of deaths taking place during the worst months of the year—namely, in February and March Then there was also a bad epidemic of measles, so that the zymotic death rate rose to the very high proportion of 4 66 per 1000 of the population Undoubtedly this prevalence of zymotic diseases was mainly caused by the principal remaining sanitary defect of Gibraltar This defect, as I explained five years ago, is in
a great m
reasons
an import
fortress, and even to day its fixed civilian population does not amount to more than 17,373 British subjects and 2982 resident aliens Between the commercial instincts and interests of the civil population and the purely military
purpose of
resulting in
which of c
want to rai
the available ground, but such structures would mask the batteries and be in the line of fire so they are forbidden, and therefore the houses remain low and small On the other hand, the commercial enterprise of the place and the openings for trade attract many persons of all conditions, from the poor Spanish labourer to the wealthy Levantine merchant. As Gibraltar is a fortress and not an ordinary colony the right of residence can be refused to foreigners and it is only in exceptional circumstances that permission is granted. But British subjects cannot be excluded It takes, however, but a short time to reach the Spanish lines on foot and costs only a few pence to go to Algeciras by steamer; therefore several thousand workmen and labourers cross every day to Gibraltar and yet do not live there. But the native born workmen and workmen from Malta, being British subjects, cannot be sent across the Spanish lines every evening and they have a right to remain in Gibraltar and claim to be housed there This it is that causes the main difficulty The overcrowding problem, acute everywhere, is particularly complicated at Gibraltar, for it can readily be imagined that in the event of another siege the smaller the number of private houses and of the civil population the easier it would be to defend the place, therefore the military authorities endeavour to keep the population down and to prevent the building of more houses As, however, it is easier to forbid the erection of a new house or the enlargement of an old one than to prevent the increase of population the overcrowding of such dwellings as exist is the natural consequence Therefore when measles or other infectious diseases occur they spread rapidly amid the over-populated and poorer districts

Putting aside the question of overcrowding as a grievance for which no remedy has been found—and one that increases rather than decreases—it may fairly be said that in most other respects there has been a marked improvement. The general health of the population therefore has greatly benefited and this is especially remarkable in respect of that peculiar local fever for which Gibraltar had acquired an unenviable notoriety This sort of remittent fever, which sometimes produces a temperature of 105° F and has often been described by Dr W Turner of the Civil Hospital, had almost become extinct He considers that, speaking roughly, its frequency must have decreased during the last 20 years in the proportion of about 90 per cent Formerly Dr Turner used to attend about 60 cases of "Rock fever" during the course of the year and now he does not see more than three cases or so in the 12 months This marked improvement he attributes to better sanitation, to the prolongation of the main sewer to Europa Point, to better house drainage, to the care taken in re arranging, trapping, and ventilating the house drains, to the better paving and scavenging of the streets, to the great improvement in the water supply, and to the more strict supervision of the food- and the milk supplies

The most remarkable of the great works undertaken of late years is that of the water supply Formerly the inhabitants gathered what water they could from the roofs of the houses and kept it in tanks below the houses, they also had private wells, though this latter supply was often brackish Of course there was every danger that such water would be contaminated On the slope of the rock a catchment area measuring some 21 acres had been marked off and reservoir tanks were constructed near the remains of the old Moorish castle which had a storage capacity of 1,257,444 gallons. This water was sold to the inhabitants at the rate of ten gallons a penny, but during the dry season the supply was exhausted and was replaced by distilled sea water which was sold at five gallons a penny So unsatisfactory was this state of affairs that on the occasion of my last visit in 1898 a plan had been adopted for covering the catchment area with concrete so that none of the water should be lost and for tunneling into the rock so as to construct therein huge reservoirs capable of storing 5,000,000 gallons of water This great work has been completed and a still greater undertaking is now in hand.

The necessity of large reservoirs for the storage of water is caused by the nature of the climate. The average annual rainfall is 33 3 inches, but it varies from a maximum of 77 inches to a minimum of 15 inches, so that it is necessary to store water from one year for the following year. Conse-
uly, 1898, miners set to work to scoop out of the
our great reservoirs identical in size and situated
The work was soon accomplished and on my
ibraltar this year I was able to visit these very
remarkable reservoirs After ascending the rock for some 300 feet the author of this bold scheme, Mr. W. Wallace Copeland, C E., the secretary and engineer of the Gibraltar sanitary board, led me through a very unpretentious doorway into a small building where four gauges on the wall indicated how much water there was in each of the reservoirs. Here also were the engines and air-condensing machines that provide the power required for drilling into the rock.

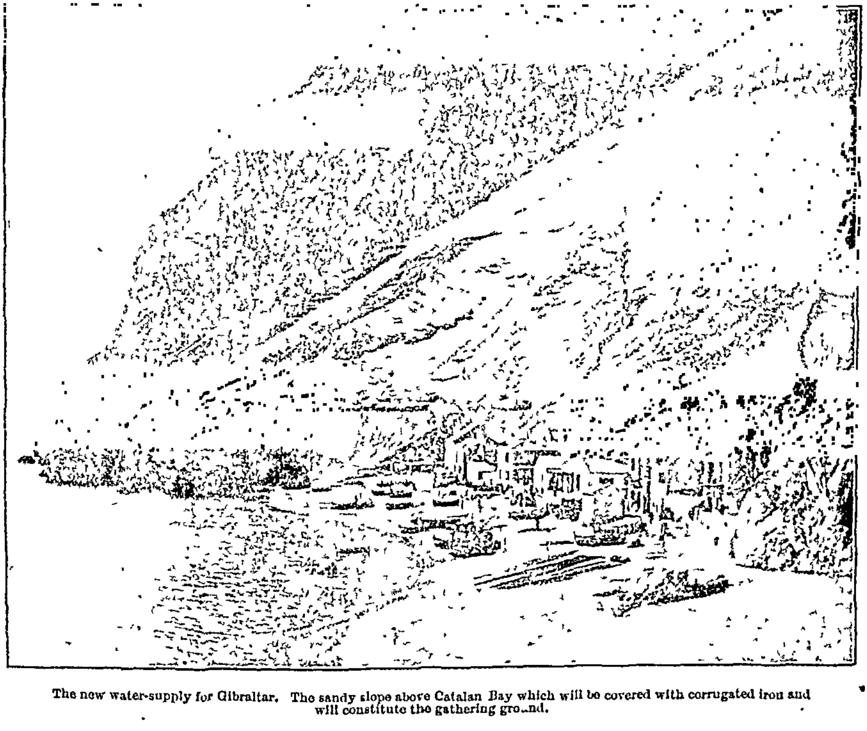
To visit the reservoirs there are a small entrance and ladders to descend. These reservoirs are at their lowest part 340 feet above the sea, they are 201 feet long, 51 feet deep, and their average width is 22 feet. Of course it is pitch dark, but there is a system for conveying electric wires to the farthest extremity so that the whole can be illuminated and a strangely weird effect is produced. The reservoir which we first visited contained 30 feet of water and a small collapsible boat provided us with the means of rowing round this lake which has been built within the rock. The next reservoir visited was quite empty and it was a long climb down the ladders to get to the bottom and thus to realise the great depth and length of the space necessary to hold one and a quarter million gallons of water. It is easy to talk in millions but very difficult to grasp and really to understand what a million means. Here, in any case, we have an object-lesson and can measure with the eye the cubic capacity of more than a million gallons. Yet to let out this vast volume of water a pipe only four and a half inches in diameter is used. The pipe that lets the water in is at least a foot in diameter, for when it rains the water comes down quickly. As it enters from the top of the reservoir it would make a waterfall that would soon damage and disintegrate the stone, so the pipe is prolonged to the bottom and is there curved round, forming a syphon. Thus the water falls on water and comes out with an upward current that presses against water and not against the walls or other hard substance. In this manner there is no shock. Nevertheless it is necessary to have a portable boat that can be taken to any of the tanks so as to watch the walls and to repair them when the damage is on a level with the water, otherwise it would be necessary to construct a scaffold within the tanks.

The gathering grounds which feed these reservoirs are carefully hedged round with barbed wire to prevent goats and other animals getting in. At the same time there is nothing to attract them. Not only has all trace of earth been removed but every crevice or fissure in the rock has been filled up with cement to prevent any lodgment of seeds or growth of any sort. Thus there is, as it were, a bald patch on the surface of the great rock and this constitutes a perfect gathering ground for pure rain-water. At the lowest extremity there is a trench to collect the water which sometimes comes down with such violence that it has been found necessary to build a wall to prevent it from splashing over. At the lower end of this trench stones closely packed have been introduced so as to act as a sort of clarifying filter, but when there is a great downpour the water is likely to leap over these pebbles. This does not matter, for it is only the first downpour of water which has washed the bare surface of the rock that needs a little clarifying. In practice the water when it reaches the reservoirs is very clear. The only thing which it has been found impossible to exclude is an occcasional olive leaf; these are so light that they float over every impediment. After passing through, and sometimes over, the pebbles the water from the gathering grounds enters a large iron pipe that passes over, and in front of, the reservoirs. Branch pipes and valves control the distribution of this water so that it may be discharged into one or more of the reservoirs. Thus the water in one reservoir may be kept quiet and untouched for some months, while another reservoir may be emptied completely so as to be cleaned out. The great object is to keep the water as it is kept by nature—that is, far away from the fluctuations of temperature or light. Even those parts of the reservoirs which are nearest are more than 50 feet away from the surface of the rock. Thus the water is not only stored well away from the effect of light and heat but it is quite safe in case of bombardment. After remaining for 12 months in one of these reservoirs the water was found to be unaltered. There was a little slime at the bottom but no animal life. Nevertheless, after drawing the water from these reservoirs and before it is allowed to flow into the distributing tank it is filtered. For this purpose there is a bed five feet deep packed with sand and polarite. When the water has passed through this filtering medium it is aerated by falling in a spray over a ledge to a depth of 40 feet. After this filtering and aerating process the water is invariably found to be perfect. Even then, the water is systematically analysed every month and after every downfall of rain. Mr. G. A. Albrines, F.C.S., M.S.P.A., is intrusted with the work of analysis. When the great reservoirs are closed in an air channel has to be provided so that air may pass in or out as the reservoirs fill or empty, but to prevent any contamination several air screens and one asbestos air filter have been placed in each of these air shafts. Thus neither dust nor flies can be drawn into the water reservoirs. Then their position, high up and within the bare rock and at a considerable distance from any dwellings, is exceptionally favourable. Indeed, these four lakes, artificially and promptly made right in the centre of the rocky mountain, are really marvellous and have an air of mystery about them that is most facinating. There are the small cave-like entrances leading to the vast deep lakes within, while without and around we have the exquisite but neglected beauty of innumerable wild flowers that wave gracefully over the surface of the majestic rocks. Below stretches the broad expanse of the blue waters, bounded on one side by the green hills of Algeciras and on the other by the towering form of Gibal Moussa which, like a natural fortress, frowns from the northern shores of Africa. Here on this rock side, but well away from the scorching rays of the sun and safe from shot and shell, can be stored 5,000,000 gallons of water. Thus when the supply is abundant some can be kept over for the next year when there may be a drought and can thus be stored in a manner which will prevent deterioration. Such was the scheme conceived some six years ago and now fully realised. It was at first thought that this supply would suffice, and so it would if it were used for drinking purposes only. For sanitary purposes—the flushing of drains and the watering of streets—there is another supply. This is obtained from the sandy plain at the foot of the perpendicular portion of the rock known as the North Front. With the aid of Worthington's condensing engines this water is pumped up to the waterworks near the Moorish tower into tanks that are 250 above the sea. This is known as the sanitary water and by gravitation it flows to all the houses. It is a brackish water so there is no danger of anyone drinking it. The amount of salt it contains varies according to the season of the year and when at its worst it contains 600 grains of salt to the gallon. The sea water at Gibraltar contains more than 2000 grains of salt per gallon. The sanitary water, though salt, is free from all deleterious organic matter and can be used for bathing purposes.

Now that the public water-supply has been so largely augmented the dangerous private wells sunk in the red sand on which the town is built have been closed. The authorities here possess absolute powers which do not exist in England and therefore were not only able to close the old supplies but to regulate the quantity that the inhabitants must take of the new supply. Thus they are compelled by law to take ten gallons of sanitary water per day for each person so that there shall be sufficient to flush the drain-pipes satisfactorily and to keep the habitations thoroughly clean. By combining the use of brackish water with that of pure water and building reservoirs for 5,000,000 gallons of drinking water it was supposed that means had been found to cope with the irregularities of the rainfall and that the problem of the water-supply was solved. But in this calculation no account was taken of the new dock works and the probable demands of local industries. As soon as the authorities found that they had more water at their disposal they also discovered that they could sell it advantageously. All persons who had engines were willing to pay for the drinking water instead of using brackish water for their boilers. This applied not only to steamships but to the great number of engines employed at the new dock works. Then there were mineral water manufacturers and others who all wanted pure water. Thus, instead of reserving water in case of drought the authorities found that they had sold far beyond the very last drop of the maximum supply and that they would be obliged to make up the difference by distilling salt water; indeed, they calculated that the demand for pure water has increased eight-fold within the last few years.

To meet these new and unforeseen exigencies another appeal was made to the inventive genius of Mr. Copeland. The result has been a proposal which for its bold daring is only equalled by the readiness with which it was approved, adopted, and put into execution by the authorities. In England or, for the matter of that, in France and in most countries such a proposal would have been debated for years before a single step was taken towards its execution. The back or east side of the rock is so precipitous that there are only two places where a landing can be effected. A good road from the North Front leads to the first of these, known as Catalan Bay, but there is only a path over the sands to the next, called Sandy Bay, and it is not possible to go any further. At Catalan Bay there is a small fishing village and above in the rock there is much quarrying work done to supply the stones for building the new docks. But on the further side of the village there is a sort of indenture or scooping out of the lower portion of the rock which is filled up with beautiful soft sand. This sand presents a smooth though somewhat moveable and unstable surface. Now Mr. Copeland conceived the idea of laying over this sandy surface a wooden framework and affixing to it a corrugated iron roofing. This would constitute a perfect gathering ground far above any habitation and on which no vegetation could grow. Then to bring the water to Gibraltar he proposed to pierce a tunnel right through the rock. Nor would this be such an extravagant process as it might seem at first sight, for the tunnel might be utilised not only for conveying the water but also as an extra reservoir. The tunnel would be 2025 feet long and would measure 10 feet in height and seven feet in width But the idea is to enlarge this tunnel for the greater part of its length and to create an elongated reservoir which will hold 17,000,000 gallons. When this is done the water difficulty will be settled for ever. Already at the time of my visit a great part of the tunnel had been pierced and it was hoped that the miners would get through the rock in the course of the month of July. The tunnel, it was estimated, would be in a condition to receive and to convey the water through from Catulan Bay to Gibraltar town by next September. At first it is proposed to cover only ten acres of the sandy gathering ground with corrugated iron roofing, but there are altogether 40 acres available for this purpose.

With the very courteous assistance of Mr. Copeland I was able to visit in detail this gigantic enterprise. On the Gibraltar side I penetrated the tunnel to a distance of 733 feet and had then more than 700 feet of rock above my head. Yet even here water was still oozing through, showing the porosity of the rock. The drilling machines are worked with air compressed to 80 pounds to the square inch and its expansion in the tunnel helps to cool and to renew the atmosphere. If steam instead of compressed air were employed this would be injurious. But the dynamite explosions which have to be produced so as to shatter the rock create very poisonous gases which cause the men to vomit and their lives can only be saved by prompt removal to the outer air. Therefore iron pipes or shafts are put down in the tunnels and carried close to where the explosions take place. At the mouth of the tunnel an oil engine causes a Blackman's fan to revolve and thus fresh air is pumped promptly and in large volumes into the tunnel so as to render the work quite safe. On the Catalan Bay side the same precautions are taken and I was able to see for myself the admirable situation of the new gathering grounds. Altogether this bold scheme is progressing rapidly and will ultimately give Gibraltar, its trade, and its shipping more pure water than it is likely to need. Therefore full provision will then be made to meet the demand during exceptionally dry seasons. Mr. Copeland, as the engineer who has devised this scheme, and the authorities who have had the courage to carry it out almost as soon as it was proposed, are to be congratulated; they will certainly win the gratitude of all who are concerned in the welfare of "The Rock."



The new water-supply for Gibraltar. The sandy slope above Catalan Bay which will be covered with corrugated iron and will constitute the gathering ground.

REVACCINATION OF TRAMPS.—As a precaution against small-pox the Christchurch (Hampshire) board of guardians recently resolved to try the experiment of having all the tramps who visited the workhouse medically inspected and, if they consented, revaccinated. The plan was tried for one month but none of the tramps would consent to the operation and the experiment, which cost the guardians about £10, was abandoned.

Correspondence.

"Audi alteram partem."

MEDICAL DOCTRINES OF HEREDITY.

To the Editors of THE LANCET.

SIRS,—Two remarkable letters under the above heading have appeared in your recent issues. One is by Dr. G. Archdall Reid (July 4th, p. 56) who asserts that evolution is caused by injurious agents eliminating the unfit, and the other is by Dr. J. Wiglesworth (July 18th, p. 186) who denies the arguments and conclusions of Dr. Reid. As both cannot be right one or both must be wrong.

Dr. Reid begins by stating that the theory of the transmission of acquired traits is now generally abandoned, but that a great many still believe (of whom he is not one) that the effects of poisons and privations on the parents affect the future offspring by their effects on the germ cells through the medium of the blood. The argument is used that the germ cells, like other body cells, must be injured by a poison such as lead, for example, and thus since the germ cells are injured the future offspring must be injured in a like manner. Now it must be noted that Dr. Reid does not deny that the germ cells may be injured by a poison or any other injurious agent; what he does assert is that it is difficult to believe that the descendants of such damaged germ cells should still continue to perpetuate the injury done long after the injurious agency has ceased to act; for if this were so in cells other than germ cells then there could be no true recovery from illness, and if it is not so in the body cells then it may be asked, why should the injury done long ago be perpetuated in the descendants of the germ cells? Further, Dr. Reid points out that asexual reproduction results in exact copies of the parent, whereas the offspring of sexual reproduction always differ more or less from the parents and from one another; that is, sexual reproduction, however it brings it about, is the cause of variation, and thus it is that many biologists have concluded that external agencies have little or no influence on offspring subsequently produced. Of course, as Dr. Reid has pointed out elsewhere, variation must in the last analysis be the result of acquired traits, but that is not the question involved here. Again, if acquired traits are transmitted and thus become variations in the second generation from the parents, then certainly all acquired traits are not transmitted—e.g., the wrinkles on the brow of an old man who has become a father or the distorted foot of a Chinese woman. With reference to alcohol and toxins, if injury is caused to the future offspring by the action of these agents on the germ cells, then this degeneracy, variation, or inborn trait is caused by an external agent circulating in the blood, and as variations are transmissible to future generations, and as these variations can either by natural or artificial selection be rendered stable in the race, it is thus that new species are evolved and the unfit individuals are eliminated, for if the offspring are injured through the germ cells by poisons circulating in the parents' blood, and as this would be a variation, and as this variation would accumulate in future generations, it follows that these future generations would become more and more degenerate in the case of alcohol so as at last to lead to extinction. If, however, these injurious agents, whatever their effect may be on the germ cells, do not affect the future offspring, and as they tend to eliminate the unfit—for example, in malaria, phthisis, alcohol, &c.—the result will be that the race will become more and more resistant to them, and this is simply natural selection. Man has undergone evolution, as is evidenced by his size, colour, and hair, but he is still evolving with regard to disease and especially so with regard to alcohol. Samuelson in his "History of Drink" has pointed out that races that have had a prolonged acquaintance with alcohol are the soberest on earth—e.g., Jews, Chinese, South Europeans, West Africans, &c.—and that this sobriety is in exact proportion to the past experience of the alcohol. The same is to be said of disease; each race is resistant to disease in exact proportion to its past sufferings from it—e.g., phthisis in Great Britain, malaria in West Africa, &c. Races that have had no past acquaintance with alcohol or infectious disease are quickly eliminated when brought into contact with them—e.g., the South Sea Islanders with phthisis and Red Indians with regard to drink. I trust this is a fair presentation of Dr. Reid's arguments—at least I believe it is as fair as could be achieved with the limited space I have allowed myself.

Dr. Wiglesworth, in his letter to you, represents Dr. Reid as asserting that the germ plasm is incapable of receiving permanent injury by the agency of poisons circulating in the blood. For this statement of Dr. Wiglesworth there is not one iota of justification. What Dr. Reid did say was, "Even if the germ cells are injured it does not follow that this injury will be perpetuated in their *very* remote descendants—i.e., in the *body* cells of the child—at a time long after the injurious agency has ceased to act." Dr. Wiglesworth concedes that the main cause of variation is bisexual reproduction but holds that there *may* be other causes. Certainly; other causes have been held, such as the accumulation and transmission of acquired traits. In support of this theory can Dr. Wiglesworth, or any other, advance one indisputable instance of the transmission of an acquired trait? Of course, it must be understood that we are at present dealing with multicellular organisms, for it is possible that in the unicellular world natural selection is by the accumulation and transmission of acquired traits, for example, the conversion of small-pox into vaccinia by passing the virus through the cow. It is not necessary to suppose, as Dr. Wiglesworth seems to think others do, "that the germ plasm is wholly uninfluenced by being placed in an adverse nutritional environment, such as must exist when alcohol or other poisons are circulating in the blood," nor yet that the germ cells "should be exempt from the operation of biological laws" (whatever they are), "and that the nature of the nutrient medium by which they live is of no consequence to them"; nor, again, "that recuperation in damaged germ cells must inevitably occur"; nor that it is a matter of indifference as regards the well-being of the offspring whether these are born of dissolute parents whose tissues are soaked in alcohol or of these same parents whilst living physiologically correct lives. Dr. Wiglesworth comes to closer grips with the question and confines his arguments to the action of alcohol as observed in the individual and in the race. He proceeds to refer to statistics of his own, tending to prove that parental drinking is a cause of filial drinking as well as of filial insanity. In a large number of those who are victims of nervous complaints, such as insanity, he finds a history of drinking in the parents Exactly so; and in another large number there is no history of parental drinking; in another where the parents have been drunken there is no insanity. Does this prove anything? If alcohol can damage the adult brain—and no one I think will question the statement—is it not as likely to damage the growing brain of the embryo? Here, however, Dr. Wiglesworth does not attempt to distinguish between variation and an acquired character. That the germ cells may be damaged by parental drinking is one thing but it is quite distinct from the damage done to the growing embryo by the habits of a drunken mother during her pregnancy. Unless Dr. Wiglesworth does this his statistics are worthless or at least cannot be relied on. If the injury is done during the growth of the embryo it is certainly not a problem in heredity. If, however, the germ cell is damaged by the alcohol and the offspring developed from these cells are more drunken than they otherwise would have been, or mentally weaker than they otherwise would have been, then it is a variation or inborn trait, and as these tend when transmitted the race would tend to become more and more drunken or more and more insane and thus tend to extinction. No doubt it would be difficult if not absolutely impossible to separate the acquired part of the alcoholic diathesis from the inborn, for the child can have no more recollection of the parent's gratification with alcohol than it can of his gratification with green cheese. If, however, the problem seems insoluble when applied to the individual it is not so when applied to the race. The Chinese, for instance, are one of the most sober races on the face of the earth; 3000 years ago they were one of the most drunken. Evolution has proceeded here in making them more tolerant of the action of alcohol or of avoiding it or both. Certainly it has not tended to make them more drunken nor insane. Races that have had no acquaintance with alcohol until recently are the most drunken on the earth and surely here filial drinking cannot be charged to the parents. Dr. Wiglesworth proceeds, however, to say that the case of alcohol is not parallel with disease, for in disease, he says, it is the younger units who are wiped out. Is this so with syphilis? He also says that alcohol comparatively seldom destroys the individual until after the procreative faculty has been more or less exercised. This certainly must happen very, *very often*, but *perhaps not* so often as Dr. Wiglesworth thinks. Even if the parent escapes, are we so sure that the child will escape also? It is surely notorious that men and women as a rule are disinclined to wed those who have become drunken. Notice must also be taken of the vast numbers of children born of drunken parents—and who, presumably, would have the inborn desire for indulgence in alcohol—who die an early death because of neglect and injury. Here nature is at work eliminating the unfit even if she has missed the parent. Dr. Wiglesworth does not believe that there is sufficient historical evidence to suggest that every member of any community has been so completely saturated with alcohol as to preclude any germ plasms existing untouched by this poison; can he name one race now sober which was not at one time very drunken? Or can he name one which had no acquaintance with alcohol once not now drunken? But what does his question amount to? Unless he can prove that the future offspring derived from germ plasm once damaged by alcohol is also damaged it has no bearing on the question of the evolution against drink. Nevertheless, as man differs immensely in his desire for alcohol there must also have been a difference, however slight, in the beginning, else the whole race would have been extinguished. Similarly, there must have been a difference in the beginning in man's resisting power to malaria, else all would have been exterminated in the regions the haunts of malaria. It is only those who varied favourably who survived and continued the race. This is as true with regard to alcohol as it is to malaria and to every zymotic disease.

One word more. Many are hoping for a time when alcohol may be banished from the face of the earth. That day will never come, for as there is as great a tendency to atavism as there is to evolution there will always be numbers who will drink simply for the pleasure of deep indulgence and of getting drunk. Nature is eliminating the great numbers who have the craving for getting drunk slowly and surely, only leaving those to survive who can drink without the desire to get drunk, such as the Jews of to-day. She could be helped, but the day is not yet.

I am, Sirs, yours faithfully,

July 19th, 1903. C. R. NIVEN.

NOT "THE USUAL BOND."

To the Editors of THE LANCET.

SIRS,—The attention of the council of the Medical Defence Union has lately been called to a case in which house surgeons and house physicians of a provincial hospital have been required by the board to sign a bond to prevent and to prohibit them from practising in the district in which the hospital is situated at the termination of their resident appointments and at any future time. I am directed by the council to ask you to allow them to warn candidates for such appointments against signing such bonds which cannot be enforced legally but which morally may prevent them from advancing their career in a district in which they might desire later to settle down. The method adopted is contrary to all ethical principles as it makes a condition which may prevent men well qualified from holding the appointments; such appointments should be open to the best candidates. It is impossible to believe that in case of breach of this bond the moneys of the hospital would be spent in obtaining, or attempting to obtain, an injunction and no medical man should bind himself down to a lay authority not to practise in a certain district.

I am, Sirs, yours faithfully,
A. GEORGE BATEMAN,
General Secretary, Medical Defence Union.
Trafalgar-square, W.C., July 21st, 1903.

THE TREATMENT OF GOITRE BY THE USE OF DISTILLED OR RAIN WATER.

To the Editors of THE LANCET.

SIRS,—I am able to add another case of goitre successfully treated by the use of distilled water to the three reported by Dr. C. A. Rayne in THE LANCET of July 18th, p. 185. I was consulted last September by a young woman, aged 17 years, who was suffering from a medium-sized goitre. The water in the village where she lived was very hard and bearing in mind the prevalence of goitre in districts where such is the case I advised her to give up entirely the local *drinking water and to drink only non-aerated Salutaris water*, which is, I believe, distilled water. She has done this since and is very greatly improved in health and the goitre has diminished both in size and in firmness—a result that I attribute to the change from a hard to a perfectly pure soft water. I am, Sirs, yours faithfully,

Lincoln, July 20th, 1903. W. H. B. BROOK, M.D. Lond.

THE PRELIMINARY SUBJECTS OF MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—It is obviously impossible to condense into a few lines all the arguments urged and points brought forward in a speech which, *horresco referens*, occupied nearly half an hour. Hence I cannot and do not complain of your report of my remarks at the recent meeting of the General Medical Council. But there is one error to which, in justice to myself and others, I must be allowed to call attention. I *did say that the examination in physics at the Conjoint* Board was a farce and I also pointed out that the board of management and not the examiners was responsible for the regulations under which the examinations were held. But I certainly did not characterise *this* arrangement as a farce, as your report makes me do, nor, as a matter of fact, were the two observations made in connexion with one another, as the process of compression would make it appear that they were. My point was that the examiners were working under rules laid down for them for which they were not *responsible*. This may or may not be a good plan; I expressed no opinion of any kind upon that question but merely stated what had been conveyed to me as a fact at the time of the inspection.

As I am writing, may I add that I certainly did not use the phrase, "sit hours to set up a more ideal curriculum," though to some extent it expresses my meaning. I feel that the first year of medical study is by no means in a satisfactory condition and that if we could attack that problem and solve it we should be doing a good piece of work in the *interests of medical education*. I sincerely hope that some settlement may now be arrived at with the Royal Colleges as the result of this recent meeting and that when that has been accomplished we may seriously devote ourselves to the task of reforming our curriculum, especially as regards the earlier subjects of study.

I am, Sirs, yours faithfully,

Birmingham, July 18th, 1903. BERTRAM C. A. WINDLE.

OCIMUM VIRIDE AND MALARIA.

To the Editors of THE LANCET.

SIRS,—I have been very much interested in the correspondence which has recently appeared in the press at home concerning the anti-malarial properties of the plant ocimum viride. This plant is a native of the west coast of Africa and glowing accounts have appeared as to its presumed anti-malarial properties. Although it does not grow in Hong-Kong it belongs to the same genus as the well-known pot-herb basil which is cultivated here. Professor Groom, *formerly lecturer on botany at the Imperial Naval College at* Whampoa, China, has written an article recently referring to the anti-malarial properties of the papaw tree. He mentions that during his stay in China he never saw any insect whatever on these trees. This tree is very common here and its well-known digestive properties are much appreciated, but on one of these trees recently two species of fly and one of ant were found. The castor-oil plant has also had its turn as being anti-malarial.

Undoubtedly the eucalyptus possesses anti-malarial properties, due, I take it, partly to the essential oil contained in its leaves but chiefly to the property it possesses of converting swamps (breeding places for mosquitoes) into dry land. If a plant could be found which possesses all the properties ascribed to the ocimum viride it would prove a great boon to the long-suffering residents in the tropics whose midnight slumbers are often disturbed by these tiresome pests (mosquitoes), not to mention the flying cockroaches and numberless vermin which infest these regions. An attempt is to be made to grow this plant here but I very much doubt whether it possesses such wonderful properties as have been described. I should not be surprised were the old upas tree to be "trotted out" as an anti-malarial agent.

I am, Sirs, yours faithfully,
J. M. ATKINSON, M.B. Lond.,
Principal Civil Medical Officer, Hong-Kong.
Hong-Kong, June 13th, 1903.

THE CAVENDISH LECTURE.

To the Editors of THE LANCET.

SIRS,—In your accurate and generous abstract of my Cavendish Lecture, published in THE LANCET of July 18th, may I correct one little error which vitiates the meaning of an important sentence. Your report runs thus (p. 141, col. 2): "Herein lies the perilousness of aortic pain to him whose heart is frail—to him, let us say, whose coronary arteries are occluded, which, by the way, is far from being a necessary consequence—and whose cardiac muscle is in decay." The sentence should run thus: "Herein lies the perilousness of aortic pain to him whose heart is frail—to him, let us say, whose coronary arteries are occluded and whose cardiac muscle is in decay, which, by the way, is far from being a necessary consequence."

I am, Sirs, yours faithfully,
July 20th, 1903. T. CLIFFORD ALLBUTT.

INCREASE OF LEPROSY IN BARBADOS, WEST INDIES, AND TWO OF THE SO-CALLED CURED CASES.

To the Editors of THE LANCET.

SIRS,—From time to time cases of leprosy are reported as cured, and it is with a view of bringing up the pseudo cure of this loathsome disease that I venture to allude to two of the numerous cases that have been brought under my notice.

CASE 1.—A negress, aged 17 years, was admitted into the lazaretto by Dr. Leonard T. F.-S. Archer, visiting physician, suffering from tuberculated leprosy on Nov. 30th, 1894. She was put upon salicylate of soda mixture and in about six months after being treated she had considerably improved and no trace of leprosy can at present (December, 1902) be seen.

CASE 2.—A negress, aged 35 years, was admitted to the lazaretto as a case of mixed leprosy on Oct. 10th, 1901. The hands were markedly "clawed" and the other signs of leprosy well marked. After one year's treatment with salicylate of soda mixture there was no trace of leprosy—she was "apparently cured."

These cases so struck me when I was acting for Dr. Archer that I spoke to him about the advisability of suggesting to the Government the construction of a separate place for the cases "apparently cured" as a means of getting the numerous cases of leprosy that are allowed to roam at large over the island into the lazaretto for treatment, and thus make some move by isolation towards the stamping out of a disease which is undoubtedly on the increase in Barbados. At the end of December, 1883, there were 72 lepers in the lazaretto and at the end of December, 1902, there were 119. The following table shows the number of fresh admissions from 1883 to 1902:—

Year.	Fresh cases.	Year.	Fresh cases.
1883	18	1893	20
1884	21	1894	22
1885	23	1895	13
1886	12	1896	21
1887	18	1897	22
1888	13	1898	23
1889	38	1899	17
1890	29	1900	13
1891	16	1901	17
1892	19	1902	24

But we cannot expect to get even a proper attempt at isolation of cases of leprosy when persons suffering from leprosy are employed in the lazaretto and allowed to live outside the institution and enjoy the liberties of ordinary persons as to marriage, &c. The cases of apparently cured leprosy, if the patients live long enough, will break out again, so I hardly think it fair for them to be written up as cured, when the disease is undoubtedly only under a temporary arrest.—I am, Sirs, yours faithfully,

FREDERICK DEANE, F.R.C.S. Edin.,
Visiting Physician (Acting), Lazaretto, Barbados, W.I.

THE FATAL EFFECTS OF CHLOROFORM ON CHILDREN SUFFERING FROM A PECULIAR CONDITION OF FATTY LIVER.

To the Editors of THE LANCET.

SIRS,—I was much interested with Dr. Leonard G. Guthrie's paper which appeared in THE LANCET of July 4th, p. 10. When I was pathologist to the East London Hospital for Children I had the opportunity of examining a case similar in many respects to Dr. Guthrie's. The history was briefly as follows. A very fat child, aged ten months, was admitted to the above hospital under the care of Dr. H. Morley Fletcher on March 16th, 1903. The mother stated that the child had suffered from a cough for a few days before admission to the hospital and had had attacks of vomiting after coughing. There had been no diarrhœa. The child was breast-fed and had always been perfectly well. The parents were healthy and also their other children. The child appeared to be very ill when brought to the hospital. The radial pulse was only just perceptible and was very rapid. The temperature was subnormal (97° F.). The child improved for a short period after a mustard bath. Physical signs of broncho-pneumonia at the base of the left lung were the only abnormal changes detected. The child gradually became more drowsy and died about 24 hours after admission to the hospital. The temperature was subnormal while under observation. A necropsy was performed about 12 hours after death. The body was covered with a thick deposit of adipose tissue. There was well-marked evidence of rickets in most of the bones. There was no discolouration of the skin or conjunctiva. Patches of broncho-pneumonia and collapse were scattered throughout the left lower lobe. The rest of the lungs were healthy. The bronchial glands were enlarged but there was no evidence of tubercle. The heart muscle and cardiac orifices were found to be normal. All the serous sacs were normal. *The liver was a pale fawn colour* and presented a most striking appearance. Sections of the organ were made in various directions and except for scattered purple dots the liver was of the same uniform colour. There was no thickening of the capsule and the liver substance was perfectly firm. No hæmorrhages were seen on the surface of the organ or elsewhere. The bile and pancreatic ducts were carefully dissected along their course but were found to be normal. The gall-bladder, pancreas, kidneys, spleen, and adrenals were apparently healthy. The stomach contained a small quantity of partially digested food, but this viscus and the whole of the intestinal tract were found to be normal. The rest of the body was quite healthy. Pieces of the liver[1] were hardened in 10 per cent. formalin and stained with Sudan III. and Scharlach. Typical large and small fat droplets were scattered diffusely throughout the liver tissue. Sections of the liver were also stained with hæmalum and eosin. There did not appear to be any hepatic tissue left; the whole of the sections were composed of clear spaces, with a few scattered nuclei and the portal canals. No granular matter was present; in fact, there was little to be seen except for the honeycombed arrangement already referred to. The fatty degeneration was uniform; both the central and peripheral portions were equally affected.

No cause could be assigned for the extremely fatty liver which I found in this case. At first it was thought that we might be dealing with a case of phosphorus poisoning, but further observation showed that there was no evidence to substantiate this view. Acute yellow atrophy of the liver might be dismissed in a similar manner. The only changes observed at the necropsy were broncho-pneumonia and rickets, but one never sees such a condition of the liver in either of these diseases. It is most probable to my mind that we have here an example of fatty liver similar to, but perhaps even in a more advanced stage, than, the condition described by Dr. Guthrie. The child had never had any chloroform and the question of carbolic acid or other poisons was stoutly denied by the mother. There is one more point I should like to mention, however—viz., the complete absence in my case of such symptoms as violent vomiting, fever, delirium, slight jaundice, &c. Trusting these few notes may be of interest to those who have read the interesting paper by Dr. Guthrie,

---

[1] The specimen is now in the museum of St. Thomas's Hospital.

I am, Sirs, yours faithfully,
LEONARD S. DUDGEON,
Superintendent of the Clinical Laboratory, &c., St. Thomas's Hospital, S.E.
July 10th, 1903.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 4th, p. 10, Dr. Leonard G. Guthrie calls attention to this subject. The paper opens up a most important question, for I fancy that most surgeons in children's practice have had the misfortune to lose cases within 48 hours of a comparatively simple operation and after the succession of symptoms described The possibility of carbolic poisoning could not, in some of Dr. Guthrie's earlier cases, be absolutely excluded, so it is of importance that instances in which this agent was not used should be recorded. The following is a case in point.

A healthy boy, aged three years, was admitted into the Manchester Children's Hospital in June, 1902, for the radical cure of a right inguinal hernia. Operation was performed two days later. The skin area was prepared by soap, spirit, and turpentine, followed by weak biniodide solution. No antiseptic was used throughout the operation which was an entirely uncomplicated Halstead's operation. There was little after-vomiting. Symptoms of restlessness commenced at the end of 24 hours, gradually progressing to coma, death taking place 48 hours after the operation. There was no marked rise of temperature until five hours before death (103° F.). Necropsy 24 hours after death showed marked congestion of the brain and membranes. The liver was of the pale buff colour described. All the other organs were absolutely healthy. Bacteriological examination of the wound and of the blood gave a negative result. Unfortunately no minute examination of the liver was made, but I remember being much struck by its remarkable appearance.

Isolated observations of similar cases have within the last few months been made and the fatal result ascribed to (*a*) some form of acetonæmia or (*b*) "the lymphatic diathesis," with the presence of an enlarged thymus gland. Unfortunately I cannot for the moment put my hand on the references to the papers, which are quite recent, with these suggestions. It may be noted, however, that Dr. Guthrie calls attention in his paper to the smell of acetone in the breath of children suffering from acute gastric catarrh and suggests that these may be the cases in which chloroform is especially dangerous. It is difficult in similar cases to the above to be convinced of the entire absence of any septic complication. Without a proper examination of the wound and the blood one is hardly justified in a diagnosis. But for this restraining influence I am afraid other instances could be rather freely collected. It is to be hoped that Dr. Guthrie's paper will bring out further evidence to throw light on a most interesting and important problem.—I am, Sirs, yours faithfully,

Manchester, July 17th, 1903. W. P. MONTGOMERY.

THE EXTENSION OF HAMPSTEAD HEATH.

To the Editors of THE LANCET.

SIRS,—Your notice about the extension of Hampstead Heath showed your sympathy with the movement and therefore you will perhaps allow me to add the names of the officers of the council and my address, to which offers of donations can be sent. The Right Hon. G. J. Shaw-Lefevre is the president, the Earl of Meath is the vice-president, Sir Robert Hunter and Mr. E. Bond, M.P., are the joint treasurers, the bankers of the fund are the London and South-Western, Limited, 28, High-street, Hampstead, and Lloyd's Bank, Limited, Rosslyn-hill, Hampstead, and I am the honorary secretary. Our first council meeting was held on June 26th but already nearly £7562 have been promised, besides £3000 conditionally offered, but that sum is a long way below the total of £48,000 that is needed. It behoves, therefore, all who care to preserve the beauty and freshness of Hampstead Heath to send their gifts or promises without delay, and if any will bestir themselves to interest others I shall be glad to send a paper giving full details, with a map, a picture of the heath and the fields, subscription forms, and any other information that is required.

It is delightful to those of us who know the lives of town workers, the stress and pain of heat and crowds and noise, to think that the tube railway will soon bring swiftly and cheaply hundreds and thousands of them out to the clean air and verdant loveliness which the Heath affords. But unless the 80 acres of the neighbouring fields are secured the large numbers will destroy the beauty they go to seek and the streets of small houses that it is proposed to build will spoil the far-famed view and defile the bright high air with smoke. It is not as one who sometimes rests in a cottage in Hampstead, but as one who often works in Whitechapel and knows the conditions of the thousands of people who live in places where flowers will not grow, that I tell of this need to the public-spirited of your readers who care to give to impersonal causes.

I am, Sirs, yours faithfully,
HENRIETTA O. BARNETT,
of Toynbee Hall; Honorary Secretary of the Hampstead Heath Extension Council.
St. Jude's Cottage, Hampstead, July 15th, 1903.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Medical Officership of Health: Retirement of Dr. A. Hill.

Dr. J. Robertson, Dr. A. Hill's successor, has now been appointed in accordance with the recommendation of the health committee reported in my last letter. It was to be expected that an officer who has occupied his position for so many years as Dr. Hill has done would not be allowed to lay down his charge without some recognition of his services. The health committee has expressed its opinion in the following resolution which was passed at its last meeting:—

> That this committee wish to place on record their deep sense of the value of the services rendered to the city by Dr. Alfred Hill during the [illegible] nt office of medical officer of [illegible] sanitary conditions of the [illegible] average death-rate reduced [illegible] happiness in his well-earned retirement from active public duties.

His colleagues in the service of the corporation have also shown their appreciation of Dr. Hill's work. The town clerk (Mr. E. Orford Smith) presided on the occasion of a presentation and was supported by most of the heads of the different corporation departments. In the course of his speech Mr. Smith made special allusion to the uniformly pleasant relations which had existed between Dr. Hill and the other officials during the 40 years of his connexion with the corporation, ten as public analyst and 30 as medical officer of health, and congratulated him upon the great decline in the death-rate which had taken place during his term of office. He presented to Dr. Hill, on behalf of the corporation officials, a silver tea and coffee service and a dozen silver teaspoons and expressed the wish that Dr. and Mrs. Hill might live for many years to enjoy the use of those articles. In his reply, Dr. Hill, after thanking his colleagues for their gift, recalled the fact that only one member of the corporation under whom he first served was still alive—Alderman Manton. He had seen all the others out and several series of them. He had at various times acted with the following chief officers: three town clerks, three treasurers, four coroners, two stipendiary magistrates, two borough surveyors, three clerks of the peace, five magistrates' clerks, four chief constables, and five chief inspectors of nuisances. The population in 1861, when he entered upon his duties, was 296,000 and to-day it was 533,000. Alluding to some of the work upon which he had been engaged Dr. Hill specially mentioned the closing of the town wells as a peculiarly arduous task, since there were 4000 of them, and an analysis had to be made of the water in each. With regard to the food of the people he had with the aid of his assistants made 20,000 analyses during his time of office. Adulteration still flourished and he was afraid that it would continue to do so as long as very small fines were inflicted. Small fines did not act as a deterrent but seemed to have the effect of encouraging it. What was wanted was an extended official purchase of articles of food. He also reminded his hearers of a part of his work which might easily escape the notice of those imperfectly acquainted with the duties of his position—viz., the responsibility and danger which he had to incur in connexion with the investigation of the dynamite conspiracy. Samples were brought to him from time to time and were of such a character that he came to the conclusion that the explosive must be manufactured in the district. That view was opposed at the time but it turned out to be correct and more than a hundredweight of nitro-glycerine was discovered. If that had exploded it would have blown the neighbourhood to atoms. Dr. Hill's quarterly report shows a further decline in the death-rate to 18·4 per 1000—the lowest on record for first quarters of the year and no less than 1·2 per 1000 below the best death-rate previously recorded in any quarter. He attributes this result largely to the character of the weather. With the exception of a short spell of cold in the middle of January the weather was remarkably mild, only ten days during the whole quarter having a temperature below freezing-point, against 31 in the corresponding quarter of 1902. In consequence of this mild weather the deaths from those diseases which are most affected by cold, such as bronchitis and pneumonia, were much fewer than usual.

The Lunatic Asylum.

Dr. E. B. Whitcombe's report for the year 1902-03 contains a number of important facts and suggestions. He states that the number of patients in the various asylums on April 1st, 1902, was 1611 and the number admitted to March 31st, 1903, was 483, making a total of 2094. There were discharged during the same period as recovered, relieved, not improved, or died, 506, so that there remained in the asylums on March 31st last 1588. The decrease in the number at the end of the year is due to the discharge of all the patients in residence who were chargeable to Lancaster and London. If these are deducted it will be seen that the number belonging exclusively to Birmingham has slightly increased. The recovery-rate for the year was 43·49 per cent. and the death-rate 14·78 per cent. He calls particular attention to the large number of male patients who have been admitted suffering from the effects of drink and says that "over 23 per cent. of the male admissions were directly from this cause, and although a large majority of these get well and are discharged, it is very sad to find that so large a number come to our institution from a purely preventable cause. The percentage of females from the same cause has, I am glad to say, been only 8 per cent. There can be no doubt that a large number of these cases go to excess as a result of previous mental weakness, but by far the greater number, I fear, are genuine preventable cases. Suggestions and remedies for the prevention of drunkenness have been made for many years and these are as varied as they are numerous. How far coercion is going to be of service in this respect remains to be seen. My experience in dealing with the insane has long led me to the conclusion that coercive measures are fatal to recovery, to comfort, and to good management, and I cannot help thinking that such measures must prove absolutely useless in dealing with those who are mentally weak enough to gradually destroy themselves by excessive drinking. One of the recent cries of the British public, and especially of the working classes, is for more amusement, and I cannot see why this should not be provided outside and distinct from public-houses, where the temptation to excess is ever present. Few temperance houses have the attractions, either in building, amusements, and other resources, which can compare with those attached to public-houses." Dr. Whitcombe points out that only nine patients out of the large population of Birmingham have been admitted during the year as paying patients. He attributes this to the fact that there is no separate accommodation for such patients and that those who are admitted are classed as paupers, a fact which relatives very properly resent. Finally he makes an important suggestion. He says, "The completion of our new asylum at Hollymoor, when it takes place, will, I hope, give the committee more time and means to carry out some of these suggestions and to bring our institution up to the level of a modern hospital for mental diseases. This brings to my mind another matter which I have long since called attention to—the name 'lunatic asylum.' The word 'lunatic' is a misnomer, so far as it relates to mental diseases, and I hope, when Hollymoor is opened, that there will be a re-christening of our old institution and that we may have the title of the 'Birmingham City Hospital for Mental Diseases.'"

Inquest on a Lunatic with Fractured Ribs.

An inquiry was held into the cause of death of a lunatic, at the post-mortem examination upon whom it had been discovered that the third, fourth, and fifth ribs were fractured, two of them close to the sternum which was also fractured. Dr. A. T. Holdsworth, who made the post-mortem examination, stated that the lungs showed signs of pneumonia and that the bones were not only exceedingly brittle but also soft. The deceased had complained that a big man had sat upon his chest. He had been in a restless state for some days and some force had been necessary to keep him in bed. Owing to the pain caused by the fractured ribs it was impossible to percuss the chest, but the presence of pneumonia was diagnosed. Dr. Whitcombe stated that he had seen cases of this kind before and the condition of the bones was such that he had no hesitation in saying that the night attendant in holding the patient and using a more than ordinary amount of force injured the chest. He had not told the attendant so; he did not think he consciously did anything of the kind. Some disagreement arose amongst the jury as to their verdict, but eventually 12 of the 15 found that the cause of death was pneumonia, that more force than necessary was used, and that death was accelerated by the fracture of the ribs.

July 18th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Royal Institute of Public Health: Congress at Liverpool.

THE annual congress of the Royal Institute of Public Health, which this year was held at Liverpool, was opened with ceremonial dignity on July 15th by the Earl of Derby, K.G., in the small concert room of St. George's Hall, academical and municipal robes being much in evidence. His Lordship, who wore the insignia of a Knight of the Garter, was accompanied by the Lord Mayor of Liverpool, Dr. W. R. Smith (President of the Institute), the Lord Bishop of Liverpool, Sir Charles Cameron, Sir Henry D. Littlejohn, Sir Charles Petrie (ex-Lord Mayor of Liverpool), Sir William B. Forwood, and the Mayors of Birkenhead, Dover, Douglas, Ossett, Lancaster, Nelson, Hyde, and Macclesfield, among others. In his inaugural address Lord Derby asked to be allowed to express his very deep appreciation of the compliment which the institute had paid him. He felt it a high honour to be able to record his name alongside those of men of such eminence and light in the medical and other professions. Proceeding to deliver his address, he said that he was not sure that we are not priding ourselves too much on the advance made. He was not sure that on ordinary sanitary questions after all we were much in advance of some nations of antiquity. It might be humiliating but it was wholesome to remember that we were not the inventors of cleanliness. The Congress was resumed on July 16th when the sections met at University College. Discussions took place on rehousing and insanitary areas, the prevention of consumption in large towns, bacteriological research under public auspices, town milk-supplies, and other subjects, concerning which your special corespondent will write with more detail. In the afternoon visits were paid to the Liverpool municipal tenements and Port Sunlight and in the evening members attended a reception given at the Walker Art Gallery by Sir William Forwood and Lady Forwood. On July 17th and 18th the meeting of sections was continued. On the afternoon of the former day a garden party given by the Lord Mayor and Lady Mayoress of Liverpool was largely attended, while on July 18th members and delegates took advantage of a variety of excursions arranged by the local executive committee to visit places of interest in the districts round Liverpool. One party visited Chester and Eaton Hall, proceeding up the river Dee by steamer, a second party visited Hawarden Castle, and a third the Norton water tower and the Liverpool pathological farm near Runcorn. There was also an excursion to Rivington waterworks on the invitation of the water committee of the city council as well as a visit to the Lancashire and Yorkshire railway workshops at Horwich. The Delamere Forest sanatorium were also visited, whilst other parties proceeded to the Isle of Man and Llandudno. On Sunday, July 19th, a large number of the members of the Congress and of the city council and other public men accompanied the Lord Mayor to the cathedral church of St. Peter where the Lord Bishop occupied the pulpit and preached an appropriate sermon to the members of the Congress. On the 20th the Section of Preventive Medicine was engaged in discussing the transmission of infectious disease, the need for greater power to cope with the spread of small-pox, and underground bakehouses. The establishment of municipal bakeries was suggested. The Bacteriological Section passed resolutions in favour of scheduling tuberculosis in animals as a contagious disease and the appointment of a Minister of Public Health. The annual Congress dinner was held in the evening at the Adelphi Hotel, under the presidency of the Lord Mayor. The company was a large and influential one. The membership of the Congress included delegates from 43 counties and county boroughs, 30 non-county boroughs, 88 urban and other local authorities, and 56 universities, colleges, and societies. The Liverpool meeting was a great success towards the attainment of which Dr. E. W. Hope, medical officer of health of Liverpool, and Dr. A. A. Mussen, his assistant, worked very hard.

Hospital Saturday and Sunday Funds.

At a meeting of the joint committee of these funds, held at the town-hall, the Lord Mayor presiding, the treasurer was authorised to make the following distribution—viz.: Royal Infirmary, £2992; Royal Southern Hospital, £2040; David Lewis Northern Hospital, £1768; Stanley Hospital, £986; Liverpool dispensaries, £816; Queen Victoria District Nursing Association, £816; Infirmary for Children, £816; Eye and Ear Infirmary, £544; Hahnemann Hospital, £544; Consumption Hospital, £476; Hospital for Women, £408; Ladies' Charity and Lying-in Hospital, £408; St. Paul's Eye Hospital, £408; Convalescent Institution, Woolton, £340, &c. The total of these sums is £13,600, being the same as last year.

July 21st.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Newport Isolation Hospital.

WHEN the Newport (Mon.) Isolation Hospital was erected in 1896 it was anticipated that the 34 beds then provided would be found inadequate to the needs of a town with a population approaching 70,000 persons. The corporation is therefore to be congratulated upon the completion of a fourth ward pavilion to accommodate 22 patients. Additions, including lavatories, bathrooms, and 21 bedrooms, have also been recently made to the administrative block. The whole institution is now lighted with electric light, an installation of 500 lamps of 16 candle power having been provided in connexion with the town mains. The cost of the original hospital was £14,132, or £415 per bed; the total cost of the hospital as now completed is £24,277, or about £433 per bed. The inhabitants of the town appear to be anxious to make use of the hospital, for in 1902 there were treated in the wards nearly 54 per cent. of the patients notified as suffering from scarlet fever, diphtheria, and typhoid fever. During the same period, of the scarlet fever patients treated at home 2·5 per cent. died, compared with a mortality of 1·9 per cent. among those treated in the hospital, and among the diphtheria patients the fatality among the home-nursed cases was 5·1 per cent., compared with 3·2 per cent. among the hospital cases.

Small-pox.

South Wales is now almost free from small-pox. In Cardiff there have been no fresh cases for three weeks, Swansea has had no cases for many months, and the disease is absent from the populous mining districts except at Pontypridd where there have been nine cases since the middle of June. All the patients have been isolated in the district council's hospital and vaccination is being largely resorted to by the inhabitants of the town. In the town of Bridgend there is one case in the small-pox hospital, the patient having contracted the disease at Pontypridd.

Swansea Convalescent Home.

It is now very generally admitted by the managers of *general hospitals* that the *most economical* method of increasing hospital accommodation is by the provision of a separate building to which convalescent patients may be removed. Such an institution in connexion with the Swansea Hospital was opened on July 17th upon a site on the hillside commanding a magnificent view of the Bristol Channel and Swansea Bay, with the Mumbles on one side and Port Talbot on the other. There is accommodation for 20 patients in two one-storey pavilions, each of which includes a ward, a day room, and bath-room, lavatories, &c., with verandahs running the whole length of the front of the buildings which have a south-westerly aspect. Between the two pavilions and connected by an open covered way is a two-storey administrative block *in which there are on the ground floor a large dining-hall for* the patients, kitchens and rooms for the staff, while on the first floor are the staff bedrooms. The cost of the building was £4100 and only about £500 of this sum remain to be subscribed. The scheme was originated about two years ago owing to the generosity of an anonymous contributor who offered through the then chairman of the hospital board (Miss Dilwyn) to give £500 towards a building fund and £10,000 to be invested for the maintenance of the institution. It is estimated that the interest on this latter sum will be sufficient to maintain ten beds, which number it is proposed shall for the present be occupied. The managers of the Swansea Hospital, unlike those of some similar institutions, have during recent years been so well able to make both ends meet that it is hardly likely that they will allow their new convalescent home to remain only partially occupied.

Swansea Hospital Operating Theatre.

The operating theatre connected with the Swansea Hospital will no doubt be visited by a large number of the members of the British Medical Association during next week. It is circular in shape and has its floor, walls, and ceiling constructed of an impervious material. There is also an entire absence of ledges and niches which act as dust traps.

Death of Trevor Halket Evans, M.A., M.B., C.M. Cantab.

The sudden death of Dr. Trevor Halket Evans of Whitchurch on July 14th, at the early age of 34 years, has deprived the neighbourhood of Cardiff of one of its most promising practitioners. Dr. Evans was a son of Mr. Franklen Evans, J.P., M.R.C.S. Eng., who retired from active practice many years ago.

Pearn Convalescent Home.

The annual meeting of the Pearn Convalescent Home at Plymouth was held on July 17th under the presidency of Admiral Wilson. The medical report stated that during the past 12 months 500 patients had been admitted; this was the largest number since the foundation of the home, and compared with 485 in the previous year. The expenditure amounted to £978 and there was a favourable balance of £192. The report of the nurses' home in connexion with the Pearn Convalescent Home showed that 111 nurses had been admitted during the year, against 85 in the preceding year; the expenditure on the nurses' home for the year was £370.

The Dangers of Ice-cream.

The inspector of nuisances has reported to the Exeter sanitary committee that in various places in the city where ice-cream was manufactured the premises were rented by Italians who provided many of their nationality with sleeping accommodation. The rooms were in a very dirty condition and ice-cream was often made in a small dirty backyard or in the common kitchen. It was suggested that the public analyst should examine some of the ice-cream so that its condition might be ascertained. The sanitary committee, after discussing the report, decided to instruct the sanitary inspector to take samples of ice-cream and to submit them to the public analyst for analysis and bacteriological examination.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Granard Guardians and their Medical Officer.

THE nursing scandal at the Granard union infirmary and the friction which has existed for months between the guardians and their medical officer have recently assumed a more serious aspect. It will be remembered that after a prolonged inquiry the Local Government Board strongly censured the guardians for what it called "a most improper attempt to intimidate an officer in the conscientious discharge of his professional duties." The Board declined to go further into the conflicting statements of the nursing sisters and the medical officer but strongly urged the necessity for harmony in their relations. The sisters, however, repeated their statements as to Dr. J. M. S. Kenny's alleged insulting language and requested the board of guardians to pass a vote of censure on him. This was accordingly done, notwithstanding Dr. Kenny's denial of the charges against him *in toto.* This strong measure did not, however, suffice in the absence of any reprobation from the Local Government Board. The sisters were unsatisfied and resigned their connexion with the hospital. Trained nurses were appointed and it was hoped that no more would be heard of the matter. After a delay of many weeks the guardians have again taken up their cudgels against Dr. Kenny in support of their former nursing sisters. At their meeting on July 6th they proceeded to suspend their medical officer and called on the Local Government Board to inquire again into his conduct. The Board replied on July 9th that after the recent full inquiry and in the absence of any additional facts the guardians were not warranted in suspending their medical officer from duty. Moreover, that the suspension had now been removed and Dr. Kenny directed forthwith to resume his duties as workhouse medical officer. Owing to the suspension of Dr. Kenny and the failure of the guardians to obtain a substitute for him the patients in the infirmary were deprived of medical aid for about four days. At a meeting held on July 14th the clerk of the union read the following letter from Dr. Kenny :—

> July 13th, 1903.
>
> With reference to the death of a patient in the infirmary named Masterson, aged 43 years, I consider it to be my duty to report the circumstances of his death. On Monday last I directed the nurse to have the patient prepared for operation on the following morning. Being suspended by your board I was unable to perform this operation. On three previous occasions I was able to prolong this man's life and relieve his sufferings by such treatment. He was left unattended to. He died in great distress on Friday evening. I send you a letter I had from the nurse in charge on Wednesday evening and my reply. I resumed duty by directions of the Local Government Board on Thursday evening. On my return I found that nothing had been done for the patients with the exception of the care bestowed on them by the nurses during the interval of my suspension.
>
> Yours obediently,
> JOSEPH M. S. KENNY.

The clerk also stated that on July 8th Nurse Gallagher wrote to Dr. Kenny stating that a patient's temperature was 103·6° F. and the pulse was 118, that he looked feverish, and that she had applied to the master for a medical man, but no medical man had appeared. To this letter Dr. Kenny replied that he was prepared to attend on requisition if the master considered it necessary. After a long and irrelevant discussion the following motion was adopted :—

> That inasmuch as an inmate of the infirmary, John Masterson, who died on Tuesday last and whose life could have been prolonged, if not saved, had there been a medical officer discharging the ordinary infirmary duty, and as the infirmary was without a medical officer from 12 o'clock noon on Monday till 4.40 on Thursday, in consequence of which an urgent operation necessary to save this man's life could not be performed, we hereby demand an explanation from the master as to why such medical officer was not procured.

The last meeting of the Granard board of guardians took place on July 21st, when a letter was read from the Local Government Board stating that it had instructed its inspector to hold an inquiry in reference to the death of the patient Masterson. It was marked "read." It seems to me that the Local Government Board is becoming more unpopular and more ineffective every day owing to its curious want of consistency and firmness. Its first letter to the Granard guardians after the conclusion of Dr. Joseph Smyth's inquiry was sufficiently strong. It informed the blundering and squabbling board that it had grossly neglected its duties, that it had incurred the punishment of dismissal, and hinted that but for some signs of improvement in the conduct of its business that penalty would have been visited on it. Now the Local Government Board has ceased to allude to anything penal, although the conduct of the guardians has become more and more hopelessly bad every week during the last two months. The Local Government Board is treated with discourtesy almost amounting to contempt and its letters are marked "read." Well may the *Irish Times*—the organ which ought to be, and usually is, the journal of the Local Government Board in Ireland—express the feeling of the public in a leading article of July 14th as follows :—

> After the proceedings at yesterday's meeting of the Granard board of guardians it becomes a serious question whether the Local Government Board will not be guilty of a grave dereliction of duty if they do not dissolve the present board and send down paid guardians to manage the affairs of the union until feeling has somewhat cooled down in reference to the scandalous dispute which has given the local board such an unenviable notoriety.

Visit of the King and Queen to Belfast.

The principal function in which their Majesties Edward VII. and Queen Alexandra are to take part in Belfast is the formal opening of the Royal Victoria Hospital and the official programme has just been issued. Their Majesties will arrive at the new hospital, Grosvenor-street, on July 27th, at 1 P.M. They will be received by the Lord Mayor (the Right Hon. Sir D. Dixon, D.L.) who will present the Right Hon. W. J. Pirrie and Mrs. Pirrie and Mr. W. Crawford (chairman of the board of management). The last-named will read an address, to which the King will graciously reply, and the following gentlemen will have the honour of being presented: the Right Hon. Thomas Sinclair, D.L., Mr. R. H. Reade, D.L., Mr. A. McDowell, Dr. J. Walton Browne (chairman of the medical staff), Sir William Whitla (senior physician), and Mr. W. Henman (architect). Their Majesties will proceed to inspect the building and in the "Pirrie Ward" Miss Carlisle will have the honour of being presented. Her Majesty will name one of the wards the "Clarence Ward," when Professor J. W. Byers will have the honour of being presented. Their Majesties will then leave the hospital through the out-patient department, where Mr. W. McLaughlin, the builder, will have the honour of being presented.

Dr. E. C. Thompson, M.P., and the Omagh Guardians.

I am glad to say that in the case in which the Omagh guardians appealed against the decision of the county court judge awarding Dr. Thompson £6 6*s.* for acting for Dr. H. B. Fleming, medical officer of the workhouse, during that gentleman's illness, Mr. Justice Madden, to whom the appeal was made, has confirmed the decree with costs.

The Purdysburn Asylum, Belfast.

At a meeting of the committee of the Purdysburn Asylum, held on July 20th, a report was received from Mr. Henry Davey, M.I.C.E., London, the expert engaged to consider the question of the water-supply for the Purdysburn Asylum buildings, in which he pointed out that there were three possible methods of obtaining a water-supply—viz., (1) by pumping from the water commissioners' mains; (2) by sinking a well and pumping from it for all purposes; and (3) by taking water for washing purposes from the brook and obtaining a supply for drinking and culinary purposes either from a well or from the water commissioners' mains, involving a double system of pipes and tanks. After fully discussing the matter Mr. Davey recommends (1) that the power for all purposes, including pumping, should be provided by steam by a system of electric distribution (a water tower having a tank on the top, with a steam-engine and dynamo in the base, with electric accumulators, would need to be erected); and (2) that borings should be made to ascertain the possibility of obtaining the necessary supply from wells and pumping this water up to the tank. It was decided to send a deputation to the Belfast water commissioners to confer as to the possibility of obtaining the required water-supply from that trust.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Hysterical Women.

ONE of the most curious, and at the same time most dangerous, manifestations of the hysterical neurosis was dealt with at the meeting of the Academy of Medicine held on July 7th by M Garnier, physician to the Depôt Infirmary. M. Garnier said that formerly the hysterical woman was considered as purely sensual, as a sense inebriate, but nowadays she was known to be the victim of an unfortunate lack of equilibrium and as one in whom the very worst disorders of sense, both motor and mental, could exist in company with the appearance of the most perfect physical health. The hysterical woman has been falsely accused, but she is, above all things, a false accuser. M. Garnier cited cases in which hysterical women had brought the most monstrous accusations

even courts of justice had been wrongly led to infer that they were true. M. Garnier considers that the mental state of the hysterical woman is that of a child with a great tendency to lie. Imagination, auto-suggestion, and hystero-suggestion find in her a fruitful field and either as witness or prosecutrix she is dangerously suspect. In any case the judge in a trial where hysterical women appear should have them examined by a medical commission as a means of protection.

Cancer and the X Rays.

At the same meeting of the Academy M. Labbé remarked that a decision had been too quickly come to as to the cure of cancer by the x rays. For his own part he thought that the cases reported by M. Vigoroux[1] were those of benign tumours which could always be removed by ordinary surgery.

The Care of the Body.

At a conference recently held at Charleville upon the necessity for personal cleanliness M. Secheret gave the following interesting statistics. 100 of the working-class population were taken at random. Of these, two took baths in a bath, 18 washed their feet when they changed their socks, 52 washed their feet twice in the winter, their bodies and neck every Saturday, and their heads never, while 28 never washed at all.

Gastrotomy for the Extraction of 25 Foreign Bodies.

At the meeting of the Academy of Medicine held on July 15th M. Monnier related a case of a young man, aged 22 years, who had been admitted to hospital for epilepsy, from which he had suffered for some time. When in hospital he was observed to have melæna but no gastric trouble. He also suffered from permanent acute pain in the left hypochondrium, together with a sensation of crepitation. The diagnosis of foreign body in the intestine was made and the patient was transferred to the surgical ward. An incision was made over the junction of the descending and transverse colon but the intestine was found to be empty, although the stomach was noticed to be full of various metallic bodies. The incision was prolonged in the line indicated by M. Labbé and an incision two centimetres long was made in the stomach. 25 foreign bodies were extracted, comprising eight coffee-spoons, the lower portion of a three-pronged fork, one staple (*patte-fiche*), two bodkins, one tooth of a comb, one blade of a knife, one needle, and one key, the total weight being 230 grammes. To extract these it was necessary to use Péan's long forceps, for the cavity of the stomach was very large. As a general rule these foreign bodies lay perpendicularly to the large curvature of the stomach and at the cardiac end. The mucous membrane was not appreciably ulcerated. The stomach was closed with three layers of silk sutures and the abdomen was closed without drainage. The patient recovered without a bad symptom and on the twentieth day he was in perfect health. He had been allowed meat to eat for a week previously. After the operation he confessed that he had swallowed all these foreign bodies some six months ago, but he could not remember how long a time he had taken to do so.

July 20th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Use of Radium in Surgery.

AT recent meetings of the Vienna Gesellschaft der Aerzte interesting discussions on the physiological action of radium took place. Dr. G. Holzknecht and Dr. G. Schwarz reported the results of their experiments made with radium on animal tissues. They had found that the majority of animal tissues, especially the vitreous body and the crystalline lens, became fluorescent and phosphorescent under the action of radium, and they therefore concluded that Dr. Londan of St. Petersburg erred in supposing that there was an irritation of the retina by the radium rays. It may be remarked that phosphorescence of the liquid contents of the eye under the influence of Becquerel rays had already been observed by the well-known German natural philosopher, Professor Giesel, some years ago. But more interesting from a practical point of view were some cases presented at the last meeting of the society by Dr. A. Exner and Dr. Holzknecht. These two physicians at first studied the pathology of the dermatitis produced by the action of radium. They found that the radium rays caused a degenerative change in the cells of the skin, in the cells of the walls of the capillaries, and in the interior of the small blood-vessels. They also succeeded in obtaining very remarkable therapeutical effects by the use of radium. Dr. Exner showed a case of Melano-sarcoma of the Skin in which an operation had been performed three years ago on the humerus and in which a great number of cutaneous melano sarcomatous tumours, varying in size from three millimetres to 1·5 centimetres, had appeared round the shoulder eight months ago. These tumours had been exposed once for from five to 25 minutes to the rays emitted by three milligrammes of radium bromide. All the tumours which had been exposed more than 15 minutes became smaller a fortnight after the exposure and disappeared after a month. At the same time only a very slight dermatitis was produced in the skin covering the tumours in question. A second similar case of melanosarcomacutis treated in the same way also showed much improvement. A third patient treated by radium rays suffered from epithelioma of the lip and had been operated on twice—namely, in 1891 and 1897. The disease recurred and there was a growth as large as a cherry when the patient was admitted to the General Hospital in May. From May 11th to June 3rd the tumour was exposed to the radium rays six times for from 15 to 20 minutes. Seventeen days after the first exposure the tumour had decreased in size very remarkably and its presence could not be recognised by clinical examination on June 26th. At the same time it was uncertain whether any cells of the new growths remained. All these cases were highly instructive as they showed that pathological formations could be destroyed by the action of radium rays without any obvious harm being done to the surrounding healthy tissues. The cases presented by Dr. Holzknecht were a successfully treated case of Psoriasis Vulgaris Gyrata (exposed for one minute), a case of Lupus Hypertrophicus of the Face (exposed for seven minutes), and an improving case of Epithelioma of the Cheek (exposed twice for five minutes). The last case presented by Dr. Holzknecht was one of Telangiectasis Plana of the Whole Left Upper Extremity and was very interesting. Eight spots of half a centimetre in diameter had been exposed for 10 minutes to the rays with the result that eight spots of the same size, consisting of perfectly normal and white skin, were visible amidst the red surface of the nævus. This case showed that the radium rays gave even better cosmetic effects than other methods of treatment. The general effect of the demonstration was to prove that radium acts as a very important remedy in many malignant diseases, in the treatment of which it will no doubt to a great extent supersede ordinary surgical methods and the application of the Roentgen rays.

Post-Graduate Courses.

Two series of vacation courses will be delivered this year, the first commencing on August 3rd and the second on Sept. 1st. The duration of each series will be four weeks. The majority of the courses are delivered either at the Vienna General Hospital or at institutes in the immediate neighbourhood of it, so that the student has not to lose time in going from one course to another. The fees for a single course varies from 50 to 100 kronen (from £2 to £4) and the aggregate duration of the lectures or demonstrations is at least 20 hours. The following courses will be given in August:—Anatomy and histology (normal), topographical anatomy and embryology, by Dr. Helly; normal anatomy of the central nervous system, by Dr. Schacherl; gross pathological anatomy, by Professor Ghon; pathological histology, by Dr. Stoerk; bacteriology, by Dr. Landsteiner; pathological dissections, by Dr. Landsteiner; pathological anatomy of the central nervous system, by Dr. Schacherl; pharmacognosy, by Dr. Hockauf; diagnosis and treatment of internal diseases, by Professor H. Schlesinger, Dr. von Czyhlarz, and Dr. Weinberger; diagnosis of heart and lung diseases, by Dr. Braun; diagnosis and treatment of gastric and intestinal diseases, by Dr. A. Schiff and Dr. von Czyhlarz; physical methods of examination, including radioscopy, by Dr. Weinberger; diseases of children, by Dr. Zappert and Dr. P. Moser; diagnosis and treatment of nervous diseases, by Professor von Frankl-Hochwart, Professor Redlich, Dr.

Raimann, Dr. Erben, and Dr. Fuchs; mental diseases, by Dr. Stransky; surgical diagnosis, by Dr. Schnitzler; diagnosis and treatment of diseases of the urogenital system, by Dr. Zuckerkandl; "atypical" operations (*in cadavere*), by Dr. Foederl; pathological histology of the eye, by Dr. Wintersteiner; ophthalmoscopy, by Dr. Wintersteiner and Dr. M. Sachs; diagnosis and treatment of external and internal diseases of the eye, by Dr. Froehlich and Dr. Hanke; ophthalmological operations, by Dr. Hanke; laryngology and rhinoscopy, by Dr. Rethi and Dr. Hanszel; rhinological and laryngological operations (*in cadavere*), by Dr. Hanszel; practical "otiatrics," by Dr. Alt, Dr. Frey, and Dr. Alexander; otological operations, by Dr. Frey; and otological operations (*in cadavere*), by Dr. Alexander.

July 16th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Accidents from Fireworks.

JULY 4th was signalised in New York by a more than usually lavish display of fireworks. There were many more or less serious accidents. In connexion with the use of toy pistols—a favourite mode by which young Americans evince their patriotism—an interesting point has been raised by Dr. Connolly, the bacteriologist of the Newark, New Jersey, board of health. Dr. Connolly stated a few days before July 4th that he had found the bacillus of tetanus in blank cartridges on sale, thereby accounting for—to his satisfaction—the origin of the lock-jaw which so frequently follows wounds inflicted by toy pistols. Dr. Park, the bacteriologist of the New York board of health, is not of the same mind with Dr. Connolly as regards this matter. He says that exhaustive investigations made by him two years ago revealed nothing of the sort and that he remains convinced that the infection comes not from the cartridge but from fragments of skin, extensively covered with dirt, which are invariably driven into the wounds. The question is one that can doubtless be settled, although on the face of it there would seem to be a stronger case for Dr. Park than for Dr. Connolly. One fact is certain—that the children of New York are given far too much licence on Independence Day. To allow young boys to carry pistols and to use them to the menace of the public is foolish in the extreme.

Action by a Surgeon to recover a Fee.

A somewhat curious case is being tried in the United States Supreme Court before Referee James E. Kelly at the present time. Dr. Manley is suing to recover $525 (£105) from the executor of the estate of the late Bridget C. Barrett. Dr. Manley's fee was for medical attendance and for operating for the removal of an abdominal cancer. Mrs. Barrett died and her husband refused to pay the bill. One of the witnesses called for Dr. Manley was Dr. Lee who assisted in the operation on the late President McKinley. Dr. Lee, in course of cross-examination, said: "The fact that the person does not live does not relieve the surgeon of his responsibility at the operation he has performed nor does it in any way mitigate his feelings; and, in fact, a man should be paid more when a patient dies than when he recovers." Dr. Lee further said "that a surgeon gets some credit if the operation is a success and is blamed if the operation does not prove a benefit and consequently surgeons have to base their charges on the responsibility they assume." At the time of writing the case had not been decided.

Floating Hospital of St. John's Guild.

Mention has been made in THE LANCET on several occasions of the work done for children in the hot weather by the Guild of St. John. During the summer a hospital for children at the seaside is carried on by this association. Last year two floating hospitals, carrying mothers and children from the tenement district of New York, sailed on every day of the week for a trip in the bay, thus affording the dwellers in this poverty-stricken neighbourhood the opportunity of enjoying fresh pure air for a few hours. Only one floating hospital will be available this summer owing to lack of funds. This decision was reached with much regret at a recent meeting of the board of trustees of St. John's Guild in order that the expenditures necessary for the summer might be kept within the limit of the contributions. The contributions received last year were not sufficient to pay the expenses of the two floating hospitals and the seaside hospital. If, however, enough money is received at an early date the second floating hospital will be put in commission.

July 10th.

Obituary.

ROBERT HALL WOODHOUSE, M.R.C.S. ENG., L.S.A., L.D.S.

BY the sudden death of Mr. Robert Hall Woodhouse at the comparatively early age of 52 years the dental profession loses one of its most distinguished members. He was the son of the late Mr. G. E. J. Woodhouse of Ansty, Dorset, and was educated at Milton Abbas Grammar School. He came to London in 1868, passed the College of Preceptors' examination, and entered at the Middlesex Hospital. He obtained the diploma of M.R.C.S. when 21 years of age and subsequently commenced his dental studies at the Dental Hospital of London. When fully qualified he entered upon private work by assisting his uncle, Mr. A. J. Woodhouse, whom subsequently he joined in partnership. He was for many years officially connected with the Dental Hospital of London as surgeon and as treasurer to the Dental School, holding the latter responsible office till within a short time of his death. He became Vice-President of the Odontological Society in 1892 and President in 1896. In 1901 he was elected chairman of the representative board of the British Dental Association. In a quiet and unostentatious way he did much to raise the status of the dental profession. He was conscientious in all his official duties, attending committee meetings and discharging all work intrusted to him with the utmost ardour and fidelity. Save that he lost two of his sons—one of whom was killed in the South African war—his private and domestic life was uninterruptedly happy. He was married in 1880 and leaves a widow, four sons, and a daughter. Though he worked hard he had the courage to take long holidays and towards the last few years of his life he reluctantly gave up to some extent both hospital and private work in obedience to medical advice. For the last two or three years his health had failed somewhat. Degenerative cardio-vascular changes, probably of gouty origin, manifested themselves, first by retinal hæmorrhage, then by mitral and aortic disease, and then by a slight hemiplegic attack. Whilst recovering from the last-named condition and whilst full of hope that he might shortly again return to work he was seized in the early hours of the morning of July 8th with an attack which was in all probability one of angina pectoris and died within the space of an hour.

Robert Woodhouse was one of the best of men. To know him slightly was to like him and to respect him; to know him well was to love him. He endeared himself to everyone by his simplicity of mind, straightforwardness, integrity, generosity, charity, and consideration for others. His charity was of a high order; when he helped one friend he did not tell another. In his official and professional life he was the very soul of honour. In a word, his personality was such that not only did it influence for good during his lifetime those who were fortunate enough to know him, but it remains in their memories and will continue its influence even though Robert Woodhouse is no more.

FRANCIS HARRISON WALMSLEY, M.R.C.S. ENG., L.S.A., J.P.

THE ranks of our profession in Manchester and Salford have again suffered grievous loss in the death of Alderman Walmsley of Higher Broughton, who has soon followed his neighbour, Dr. R. Crean. He was only taken ill on July 12th and died on the 16th. He was in his seventy-fifth year, but his neat, alert figure and air of activity told little of the weight of years. His father was a medical man, living in Dale-street, not far from the present infirmary, and there Walmsley was born. He decided to enter the medical profession, became a student at the Pine-street School of Medicine, now merged into the medical department of the Owens College, and at the Manchester Royal Infirmary, and became qualified in 1849, soon obtaining an extensive practice. In 1855 he was appointed one of the honorary surgeons to the Salford Royal Hospital, and after many years' service became one of the consulting staff. He took an active interest in public health, was one of the early members of the Manchester and Salford Sanitary Association, and was for a time one of its honorary secretaries. Though having the cares of a large and important practice he set an example of public-spirited activity in municipal work which, if it were more frequently followed by medical men, would be for the great good of the community. So far back as 1864 he was elected a member of the Salford town council, where he soon showed his interest in sanitary and educational matters and discussed them with an ability which "speedily obtained for him recognition from his colleagues as an authority on sanitation and health." At his death he had been an alderman of the borough for nearly 30 years. Soon after the passing of the Public Health Act, 1868, he submitted to the council a scheme, which was carried out, for the formation of a health department and the appointment of a medical officer of health. The question of river pollution has always been a serious one for Manchester and, Salford and Mr. Walmsley laboured hard for many years in the cause of purification, being an early member of the Mersey and Irwell Joint Committee and acting for some time as chairman of its chemical section. In 1877 he became chairman of the health committee of the Salford corporation and chairman also of the river Irwell conservancy committee. He was also one of the commissioners for dealing with the upper reaches of the Mersey. In 1876 he became Mayor of Salford and at the request of the council held the office for a second year. During these two years many important undertakings in connexion with Salford were completed. He was an ardent advocate and one of the original promoters of the Ship Canal. For many years he *was an active member of the first School Board in Salford* and later he was a representative of the magistrates of the borough, one of the governors of the Manchester Grammar School, and also a governor of the Owens College. He was an old member and ex-President of the Manchester Clinical Society, of the Medico-Ethical Society, and of the Certifying Surgeons' Association, and at the time of his death was President of the Medical Guild. From the year 1877 he was one of the magistrates of the borough and took his full share of magisterial work in connexion with asylums, &c. He was a generous supporter of many philanthropic institutions and, as one of the Manchester papers says, "his loss will be felt by the poor as keenly as by those in the very wide circle of his many admiring friends." At the conclusion of the business of the Salford Police-court on July 17th, Mr. Makinson, the stipendiary magistrate, referred in sympathetic terms to Mr. Walmsley's death, to his kindness, and to his having been for many years "one of the most useful, honourable, and upright members of the Salford corporation." One of his brother magistrates also bore testimony to his painstaking, judicious, and discriminating action as a magistrate and said that his "self-denying labours in the interest of the borough for a period of 40 years had rarely been equalled by any other citizen." He was buried at St. John's Church, Higher Broughton, of which he was one of the trustees and an old member of the congregation; his funeral, which was largely attended, gave evidence of a widespread *feeling of* respect and sorrow.

A MEMORIAL WINDOW TO THE LATE MR. T. SMALLHORN.—On July 10th a stained-glass window which has been inserted in Eynsham parish church, Oxford, to the memory of the late Mr. Smallhorn, was unveiled and dedicated. The central figure in the window is that of Christ on the Cross, with St. Mary and St. John on either side at the foot. The four top lights are filled with the figures of St. Leonard (the patron saint of the church), St. Stephen (the first martyr), St. Alban (the first British martyr), and St. Augustine (the first Archbishop of Canterbury). At the bottom of the window two angels bear a scroll with the inscription: "To the glory of God, and in loving memory of Thomas Smallhorn, for 37 years medical practitioner of this district, who died February 9th, 1902, aged 63, this

Communications, Letters, &c., have been received from—

Presidential Address

ON

THE EVOLUTION OF ANTISEPTIC SURGERY AND ITS INFLUENCE ON THE PROGRESS AND ADVANCEMENT OF BACTERIOLOGY AND THERAPEUTICS.

Delivered at the Seventy-first Annual Meeting of the British Medical Association on July 28th, 1903,

By T. D. GRIFFITHS, M.D. Lond., M.R.C.S. Eng.,
PRESIDENT OF THE ASSOCIATION.

Ladies and Gentlemen,—I have chosen for the subject of my address the evolution of antiseptic surgery and its influence on the progress and advancement of bacteriology and therapeutics and the further practical application of our knowledge for the benefit of mankind. This subject is no doubt full of interest to us all, but it is far too extensive to be treated fully in the short space of time in which I have the honour of addressing you.

In the first place, I must ask your indulgence to bear with me for a few minutes in reminding some of you of the practice of surgery as we witnessed it in the best London hospitals some 40 years ago. There are probably many of the younger members of the profession who have no conception of the condition and state of things in surgical practice even at so recent a period. During my student days in the latter end of the "fifties" and early "sixties" the large wards of our hospitals were filled with all sorts of cases indiscriminately—simple and compound fractures, suppurating joints, traumatic, senile, and hospital gangrene, erysipelas, septicæmia, pyæmia, and cases operated on for accidents and diseases, all of which were dressed by the same attendants. Each ward had its set of sponges for the purpose of dressing wounds and these were used indiscriminately for the various cases under treatment. There was no such thing as absorbent cotton wool in those days and great economy was observed in the use of lint. Linseed meal and charcoal poultices were frequently employed to sweeten and to cleanse wounds and to encourage healthy suppuration. "Laudable pus" was a sign of good dressing and healthy action. The operating theatre was often crowded with students from the dissecting-room, and at the operations the great surgeon invariably wore, with evident pride, the same old black frock-coat, buttoned up to the chin, which was kept ready for the occasion in the anteroom and which was well stained and saturated with blood and discharges. It is unnecessary to give a detailed account of the operations, but I may mention that the sponges which were used in the wards were also used at the operating table. Stout silk ligatures were employed to tie the blood-vessels and were left hanging out of the wound to be pulled at from day to day until they were separated by the process of suppuration. I well remember listening on one occasion to a clinical lecture on pyæmia which was delivered by the senior surgeon of a London hospital who confessed to the students that the causation and vagaries of pyæmia were inexplicable. To illustrate this remark, he reminded his class of a strong, healthy young man who had been admitted into the hospital for a trifling accident and who died shortly afterwards from pyæmia, while a middle-aged, drunken, abandoned woman in the adjoining ward was convalescent after a serious operation.

The dawn of antiseptic surgery was now not far off. Schwann's discovery of organic germs in the air led Pasteur to formulate a theory that fermentation is never excited except under the influence of microscopic organisms, and, further, that each particular organism sets up a peculiar species of fermentation. In 1861 Pasteur published the result of his researches on fermentation and in 1863 he demonstrated that putrefaction was caused by minute organisms suspended in the air. Prior to this oxygen had been regarded as the agent which produced it. Lister, now aided by the result of Pasteur's researches, devoted his talent and energies to solve the problem of inflammation and its attendant suppuration in wounds. He was not long in arriving at the conclusion that it was due to bacterial action —putrefaction—and he naturally evolved the idea that if putrefaction of blood serum and destroyed tissue in wounds could be prevented nature would repair the parts much in the same way as she does in cases of simple fracture. He applied this principle to the treatment of wounds in his practice in the surgical wards at the Glasgow Infirmary and afterwards in Edinburgh, using carbolic acid as his antiseptic agent.[1] At the annual meeting of this Association held in Dublin in 1867 Lister communicated to the world the result of his investigation and clearly enunciated the principles of antiseptic surgery which we recognise and practise to-day. Naturally the practical application of these principles has since been gradually modified and improved. The use of the carbolic spray, which was at first a prominent feature of Lister's method, was gradually discontinued. It was found very inconvenient in practice and not so necessary as had been anticipated and it was finally renounced by Lister himself in 1887. When the spray was given up greater attention was paid to the purity of the atmosphere in the hospital ward, and more especially in the operating theatre, and of the instruments and dressings. Then, by a natural transition, attention was turned to the possibility of asepticism, with the view of discarding antiseptics at operations and for the dressing of wounds. After some experience, not a few argued that the acme of success in surgery could be attained by the proper use of aseptic means. There is no doubt a great amount of truth in this but not to the extent claimed by the advocates of asepticism. It must be admitted that the purest air which we can obtain in the operating theatre contains micro-organisms and some of these must alight on the surface of exposed wounds. Fortunately, there is far less danger of septic action being set up by micro-organisms floating in the air than by those which are conveyed to the wound by a foreign substance. The reason of this is probably that the pathogenic micro-organisms suspended in the air are less numerous and, as a rule, less active than those which rest on solid or liquid substances. When no antiseptic lotion or swabs are used the aerial micro-organisms settling in the wound are left to the digestive cells or phagocytes to be disposed of. In ordinary circumstances and with proper aseptic precautions they are able to do so; but it cannot be denied that this delegation of trust to the cells, coupled with the possibility of imperfect sterilisation of the skin and materials used at the operation, involves greater risk of disasters (such as are not unknown to some of us) than when antiseptic means are also used. We must be careful that the pendulum does not swing too far to the aseptic side. It is at all times a difficult matter to guard the surgeon's work effectually by means of sterilisation against every possible access of pathogenic micro-organisms. Why should one trust to asepticism alone when the position can be made impregnable by the assistance of antiseptics which are practically harmless to the healing process? It is therefore evident that the acme of safety is secured in operative surgery by the judicious application of the two principles advocated and practised by Lister. The architect has been very rightly called into service to further the practical application of Listerism. This is especially to be noticed in the construction of modern hospitals and in the addition of new operating theatres to old institutions. They are invaluable in surgical work. Some 36 years ago the mortality from major operations in the London hospitals was about 33 per cent. This high mortality after major operations is now reduced to about 3 per cent., and after minor operations practically to *nil*, as the outcome of Lister's antiseptic principles.

Nursing Institutions and Surgical Homes.

We are now doing, with the aid of public charity, all that science up to date can do to help the poor. Let us now consider for a moment what has been done, what is being done, and what should be done, to meet the requirements of the middle classes for medical and surgical aid in time of need. Their own homes, or perhaps lodgings, are often unsuitable for operative surgery or for serious medical cases requiring skilful nursing. There are, it is true, many surgical homes in our large towns [illegible] ns, mere private ventures [illegible] mendation. I may, pe [illegible] very briefly what provision we have at Swansea for paying patients and for nurses. We have a dual institution—a nursing institute and a surgical home in one. This institution is supported to a very small extent by public subscription. It is managed by a small committee elected by the subscribers and is worked by a resident matron. The nurses are allowed practically all the privileges of a coöperative nursing institute and receive all their earnings with the exception of the incidental expenses of the home. The public is in this way supplied with efficient nurses whose training and character are guaranteed by the institute. The house adjoining, and communicating with the nursing institute, is provided for paying patients who are attended by their own medical men. The tariff varies from three to five guineas a week according to the requirements of the patient.

---

[1] Carbolic acid was used for some time in this country in a diluted state to preserve pathological specimens before Lister introduced it as an antiseptic agent in the practice of surgery.

Although differing from it in some details, the main principle of this dual institution is the same as that of the Home Hospital in Fitzroy-square, London, which was established by Sir Henry Burdett some 26 years ago, and which is now managed by a registered association without profit. Dual institutions, of the kind we have at Swansea, provided with a Listerian surgical home equipped with all the necessary modern appliances, are very much needed in towns to replace many private nursing institutes, some of which are now flourishing by imposing, on the invalid public, women imperfectly trained as nurses, who are engaged at low wages to be let out on hire like cab-horses for gain, and also to replace many of the so-called surgical homes which are totally unsuitable for operative surgery. Self-supporting institutions of this kind must be started in our country by public subscription or by the beneficence of individuals. A certain number of subscribers should be enrolled to elect a committee of management or to form an association, certain advantages being assured for the subscribers. The public would in this way provide for itself a nursing institute and surgical home at minimum cost, with all the advantages of a Listerian hospital, equipped with every modern appliance, and every patient would be able to employ his or her own medical man. As soon as the institution has become self-supporting the small amount of subscriptions contributed for the purpose of securing a trustworthy committee of management and any profit made should be allowed to accumulate for the purpose of extension or the improvement of the building. No party feeling should be allowed to interfere with the management and one or two medical men, elected annually or biennially, as representatives of the profession in the district, should act on the committee of management. I make this suggestion advisedly, as all the medical practitioners in the district would be more or less interested in the institute. It would be wise to avoid every possibility of friction or jealousy in the working of an institution of this kind, which is for the benefit of the public as well as being a great convenience and advantage to the local practitioners.

BACTERIOLOGY AND IMMUNITY.

The brilliant discoveries of Pasteur and the evolution of antiseptic surgery by Lister gave a great impetus to the study of bacteriology, with the result that new and unexpected discoveries were made as to the part played by bacteria in nature. We now find that these micro-organisms have a definite and important place in the scheme of nature. They are distinctly separated by gradation from both the vegetable and animal kingdom. They form a kingdom of their own which we may term the "bacterial kingdom." Their very existence appears to be antagonistic to both animal and vegetable life. Their main object in nature is evidently one of destruction—the breaking up of complex molecules of animal and vegetable substances into simpler combinations. They are nature's scavengers and undoubtedly they are the causal agents of all the communicable diseases to which flesh, and not human flesh alone, is heir.

The varieties of bacteria, differing in size, form, action, character, and power for good or evil, are almost endless. The bacteria with which we are familiar measure from 1μ to $5\mu = \frac{1}{25000}$th to $\frac{1}{5000}$th of an inch. If each bacterium measured $\frac{1}{10000}$th of an inch in length and $\frac{1}{25000}$th of an inch in breadth it would take 250,000,000 of these micro-organisms to cover one square inch of glass. These micro-organisms grow with great rapidity—a bacterium may reach maturity and divide or split into two in 20 or 30 minutes. If it divided into two every half hour it would produce a colony of over 16,000,000 in 12 hours. It has been shown in the laboratory that the growth and rapidity of reproduction and the character of bacteria depend upon their surroundings and that their virulence may be attenuated or increased according to circumstances. It is therefore evident that the law of evolution and involution of the animal and vegetable kingdoms applies also to bacteria. Supposing that the evolution of a new species of plant—say an annual—takes 336 years, then if the law is equally applicable to micro-organisms a bacterium in favourable circumstances would take only one week to run through 336 generations, provided it took only 30 minutes to reach maturity and division, and so a new species might be thus rapidly evolved.

I wish also to remind you, for the purpose of my argument, of the important fact that a bacterium may have two states or stages of existence. One is the active or vegetative stage and the other is the spore or resting stage. In the latter state, which may be compared to that of a hard nut or seed, it may remain dormant for a long time until the surroundings favour its development into the active state. This, as I shall show, has an important bearing on the treatment and etiology of specific diseases. Pasteur's and Davain's discoveries led up to Koch's investigation. Davain discovered bacteria in the blood of animals suffering from anthrax in 1863, thus confirming the observations made by Pollender in 1849 Koch repeated the experiments and finally established in 1876 the causal relationship of bacteria and disease. Tuberculous disease had been proved by Villemin to be inoculable and in some countries it had long been believed to be infectious, but it remained for Koch to demonstrate in 1882 that tuberculous disease was due to the agency of a micro-organism. He proved that a bacillus played a part in the production of tuberculosis which is analogous to that which is played by torula cerevisiæ (yeast bacillus) in fermentation. The tubercle bacillus feeds, grows, multiplies, and produces its toxin at the expense of the surrounding tissues very much in the same way as the yeast bacillus feeds, grows, multiplies, and produces its toxin (alcohol) at the expense of the saccharine solution in which it is placed. The principle discovered by Pasteur in the processes of fermentation and putrefaction was proved, after years of close investigation by Koch, to be absolutely identical in the development of tuberculous disease in the animal body. He demonstrated the bacillus in the tissue and cultivated the organism outside the body and observed the formation of the toxin. The same remark may be applied to diphtheria (diphtherisation). The diphtheria bacillus grows, feeds, and multiplies on the mucous membrane and there forms its toxin. If we compare the processes of fermentation, tuberculisation, and diphtherisation a little further we may gain an idea as to the nature of immunity which is far more rational than any of the numerous and complicated theories and suggestions already proposed. After a certain stage of fermentation the torula cerevisiæ (the fermenting agent) ceases to act, it becomes inert, and falls to the bottom of the vat. Tubercle bacilli and other pathogenic bacteria behave in exactly the same manner. After a certain stage of crowding and production of toxin they become inert and are at last practically killed by their own poison. The same thing happens in the overcrowding of animals. When yeast has ceased to perform its functions in the vat the alcohol (fermentation toxin) which it produced, if not protected artificially, is attacked by another bacterium, the germs of which are always at hand, and it is soon reduced to vinegar, which possesses different properties. Even if more must is added to the vat the acetic acid fermentation will continue. It is well known that the toxin produced by one bacterium can be destroyed or metamorphosed by the action of another. Advantage has already been taken of this power by sanitarians for the disposal of sewage, aerobic and anaerobic bacteria being called into service to do the work desired. When the pathogenic bacteria are destroyed by their own poison and when this poison in its turn is metamorphosed into a simpler compound by other bacteria, in the same way as alcohol is changed into vinegar, the patient is convalescent and as long as the spores of the second bacteria remains in the blood the patient is rendered immune[2]; but if the toxin of the first pathogenic bacteria has been removed by the leucocytes or destroyed by the oxygen of the red blood corpuscles, or, in fact, digested, or if the spores of the second set of bacteria are no longer retained in the circulation or tissues of the body, the patient has no immunity. When the germs which secure immunity become attenuated the immunity is lessened and when they are destroyed the immunity is lost for the time.

---

[2] Rheumatism produces immunity to tuberculosis and vice versa.

In convalescence after diphtheria the toxin, which may be called for convenience sake "diphtherin," is no doubt metamorphosed and its toxic character is destroyed by another ferment, and the new or metamorphosed product may be called "met-diphtherin." As long as the met-diphtherin or its causal agent remains active or dormant it confers immunity on the individual body which it occupies. Diphtherin antitoxin is the met-diphtherin obtained from the blood of the horse, which confers immunity on the human subject. When this is used at an early stage of diphtheria it damages the vitality of the diphtheria bacilli and reduces their diphtherin to met-diphtherin which is harmless. Pasteur demonstrated that when grapes are ripe in October a large number of the berries and their stems have their skins covered with spores of torula cerevisiæ ready to develop under favourable conditions. This happens immediately when the grapes are crushed and the solution is kept at a proper temperature. He also demonstrated that yeast can be weakened (attenuated) by nursing it in a weak solution of sugar until eventually it is unable to cause any fermentation. We may also study with advantage the processes of sporulation and vegetation of yeast cells, which are analogous to those of pathogenic bacteria. By the process of sporulation the yeast cell contracts and hardens like a grain of corn and retains its vitality in this condition for months or years. The same is also true of pathogenic bacteria which exist either in the state of vegetation or sporulation.

Professor G. Sims Woodhead pointed out at our annual meeting last year that diphtheria bacilli may remain dormant in the throat for months. This is an important fact worth remembering, inasmuch as it may account for anomalous outbreaks of acute specific disease.

Considering the rapidity with which bacteria grow and attain their maturity and multiply, and considering how easy it is to attentuate or to increase their virulence, it is logical to infer that the process of evolution may be brought about very quickly, as has already been pointed out. It is therefore natural to infer that, under favourable conditions, bacillus [illegible] into bacillus typhosus, both [illegible] ppearance, and the so-called [illegible] phtheria bacillus, which are also alike in appearance, &c. Like the ripe grapes with germs of yeast in the dust on their skins and the surface of their peduncles, we also have germs of specific diseases about us which only require certain conditions to develop them. The late Sir James Paget, in his memorable address at the International Medical Congress in London in 1881, dwelt at some length upon the importance of studying the physiology and pathology of plants to help the advance of knowledge of human pathology. Nature always works on definite plans but with ever-varying difference.

THERAPEUTICS.

Both bacteriology and Listerism have greatly helped to advance our knowledge of the action of medicine. Therapeutics have now been raised in many departments from the plane of empiricism to that of science. Peruvian bark, the active principle of which is quinine, was accidentally discovered to be of great value in the treatment of malarial fever. The discovery was the result of observation, but the knowledge gained was entirely empirical. Prior to the discovery of the hæmamœba and the observation of its action on the red blood corpuscles, and until the Listerian property of quinine was ascertained, we had no idea how the drug acted as a curative agent. It is now evident that it acts simply as an antiseptic in destroying the malarial parasites which are conveyed to the human body by mosquitoes, and [illegible] her it has any other beneficial [illegible] The world is greatly indebted [illegible] ne we were glad to see in the [illegible] and to Major R. Ross for their discovery of the part played by mosquitoes in the causation of malarial fever.

Very much the same remarks may be applied to salicin, salicylic acid, and the salicylates, which are powerful antiseptics. The discovery that these drugs were specially valuable in the treatment of rheumatic fever was accidental also. It is now acknowledged that rheumatic fever is due to a micro-organism which probably gains access to the circulation through the tonsils or mucous membrane of the pharynx. Sore throat is a frequent precursor of acute rheumatism. It is probable that scarlatinal sore throat predisposes the patient to infection by rheumatic micro-organisms, over which the salts of salicin have a lethal action.

Mercurial salts are the most efficient antiseptic agents we possess in surgical practice and it may be argued that the therapeutic action of mercury, when administered internally, is to be accounted for, to a great extent, by its antiseptic property; hence its specific action on syphilis, which is now stated to be a bacterial disease. It has been recognised for many years that mercury is a valuable remedy in tonsillitis which is also, no doubt, caused by micro-organisms. Dr. Jamieson of Edinburgh pointed out some years since[3] that mercuric chloride is most valuable as a bactericide in the treatment of scarlet fever. Arsenic, like mercury, a valuable remedy, is a powerful bactericide. It has been stated lately, on very good authority, that it is useful in the treatment of tuberculosis. It is well known as a most valuable remedy in malarial diseases. Its lethal action on other micro-organisms, which we have not yet discovered, may account for its therapeutic value in the treatment of anæmia, pernicious anæmia, skin diseases, and degenerative changes which are attributed to "premature old age." It is possible, and very probable, that micro-organisms are active agents in the production of atheromatous changes in the vascular system. We now acknowledge that the deposit of tartar on the teeth is the product of certain bacteria; even the gouty deposit in various tissues of the body should probably be credited to some as yet unknown bacilli. In any case, the facts before us are sufficient to justify the suggestion as a working hypothesis. Iodine is another powerful antiseptic agent and a cell stimulant favouring absorption of exudative and inflammatory products; as it possesses these two properties to a high degree and is readily tolerated by the animal economy it ranks among the most useful remedies we have in our Pharmacopœia. Iron may act as a powerful antiseptic remedy indirectly. In cases of anæmia it improves the condition of the red blood corpuscles which are the carriers of oxygen in the animal economy.

The most approved local treatment of skin diseases, as well as those of the mucous membranes, may be briefly stated to be a judicious use of antiseptics alone or in combination with some sedative or stimulating agent as the case may require. All the useful remedies we employ in the treatment of inflammatory trouble of the genito-urinary passages are antiseptics and although the amount which is passed by the urine is very small and much diluted, yet it is sufficient, within a certain limit, to destroy by degrees the offending bacilli. This gradual process of destroying bacteria can be imitated in the laboratory. The virulence of bacteria can be attenuated by growing the organism in the presence of weak antiseptics and can be weakened also by injecting certain chemical substances along with them into the animal body. All conditions which are unfavourable to the growth of bacteria attenuate their virulence, render them innocuous, and finally destroy them. Sunlight and the Roentgen light are fatal to bacteria. The open-air treatment of consumption, which is a combined aseptic and antiseptic treatment, is an illustration of the value of light, pure air, and ozone. The effect of heat and cold on bacterial life is a most interesting and important subject. Every species of bacterium has its latitude of temperature in which it can flourish, a few degrees above or below being fatal. Bacteria differ in their power of resistance to the toxic action of antiseptic agents. Tubercle bacilli are readily destroyed by iodoform, while other micro-organisms flourish in it Even mercuric chloride solution of moderate strength does not kill all bacteria equally quickly. Time will not permit me even to enumerate, much less to expatiate on, all the antiseptic agents which we have now at our command. We now see that Listerism is as valuable in the practice of medicine as it is in surgery.

PUBLIC HEALTH.

The practical application of our knowledge for the benefit of the public health has not kept pace with the great progress made in medicine and in surgery during the last 36 years. The Public Health Act of 1875, which was very comprehensive and well conceived, has been of great service in improving the sanitary condition of urban and rural districts; but in spite of the amending Acts, and in spite of the Local Government Act of 1894, it is now clear that both the law and its administration are defective in many points been gained. This applies emphatically to the whole range of complaints with which I am now concerned, for the term "infective," according to modern teaching, has come to have a very precise pathological signification, founded on a scientific basis, and the outcome of the researches and experimental investigations of Pasteur, Lister, Koch, and their followers. To this doctrine the medical faculty generally, with but comparatively few exceptions, has given its cordial and uncompromising assent. It affirms that every infective disease is the result of the direct action upon the body of one or more living pathogenic micro-organisms or bacteria and in many instances it has been positively demonstrated that a specific organism is the cause of a particular disease and of no other. It must be clearly understood that according to this definition the term "infective" is not synonymous with "infectious," which implies that a complaint is capable of being communicated, either by direct inoculation or contagion, or indirectly in various ways, from person to person, or from some other animal to man. In short, an infectious disease must be infective, but an infective complaint is not necessarily infectious.

---

[3] Brit. Med. Jour., 1887.

I need scarcely remind you that a number of contagious diseases have long been known to be due to obvious or easily demonstrable parasites, animal or vegetable, and it is interesting to note in passing that the investigations of recent years have added, and are still adding, to the list, of which actinomycosis may be cited as a conspicuous example. The organisms which we are now dealing with, however, are on an infinitely more minute scale and the profession as a body has to accept in the main what trained bacteriological experts tell us about them, their toxins, pathological effects, antitoxins, and other details. The theory of *contagium vivum* is of very ancient date, but the positive demonstration of the nature of the so-called virus was only started and has been progressively accomplished well within the last half century, while the investigations which are still going on in all directions are adding daily to our knowledge and to the practical results following therefrom. These investigations, however, have shown that there are still not a few difficult questions to be solved and we must be on our guard against too hasty conclusions or generalisations on insufficient data. It is a remarkable fact that in the case of some of the most prominent infectious diseases with which we have long been familiar no definite or specific organism has thus far been recognised, at least so as to be acknowledged by competent and trustworthy authorities, and we cannot accept the alleged discovery of such organisms in individual complaints unless and until they have received the stamp of the approval of such authorities. At the same time we may be certain that they exist, and this fact may be accepted as the basis of a sound working hypothesis.

When we look back upon the history of medicine during the past half century, but more especially during recent years, we cannot avoid being struck with the additions which have been made to the group of infective and infectious diseases and with the way in which others, though previously known, have come so much more prominently to the front. The multiplication of these complaints has been partly due to the differentiation of diseases which were formerly regarded as identical as the result of careful and systematic clinical observation and post-mortem examination. It is, however, to the revelations of bacteriology that we mainly owe these additions which in the first place have brought all inflammatory, suppurative, and septic conditions within the infective group. Among special medical diseases coming under these categories which, according to modern views, are thus definitely classed as infective may be mentioned pneumonia, rheumatic fever, gonorrhœal synovitis, possibly rheumatoid arthritis, malignant endocarditis, certain acute throat inflammations, and different forms of meningitis. But, further, bacteriology has proved conclusively that several unsuspected complaints or morbid conditions are infective or even infectious, of which the most remarkable are tetanus, tuberculosis, and malaria. Influenza and diphtheria are striking examples of infectious diseases which seem to have developed into terrible scourges within living memory, though they are by no means new complaints, and their prevalence can be easily explained in the light of modern knowledge. Anthrax and glanders have come to the front because they illustrate in a remarkable way certain important points relating to the pathology of micro-organisms. Glandular fever, specially studied in this country by Dawson Williams, is an interesting addition to the acute infectious diseases. I have already alluded to malaria, and I wish now to draw special attention to the fact that the effects of this condition as well as several diseases always known to be infectious, such as cholera, dysentery, plague, and yellow fever, which originate and prevail chiefly in tropical or subtropical countries, and with most of which we as a nation had formerly little or no direct concern, have nowadays assumed a conspicuous prominence and have become of extreme practical importance. New diseases belonging to this category have also been, and are still being, brought to our notice, such as blackwater fever, Malta or Mediterranean fever, trypanosoma, sleeping sickness, and beri-beri. So important have they become that "schools of tropical medicine" have been, as you are aware, established in different places for those who need special training in relation to these diseases. The free intercommunication which now exists between Europe and tropical countries, many of them far distant, has brought these complaints to our very door, so to speak, and we are compelled to deal with them seriously and to do what lies in our power to cope with them. And more especially Great Britain as a nation cannot ignore these complaints, as many of the regions in which they prevail form an integral part of this vast empire. We are, I presume, most of us "Imperialists" nowadays, but in this relationship, at any rate in existing circumstances, no one dare be a "Little Englander." We cannot evade the responsibilities which the Imperialistic sentiment brings with it with regard to these terrible diseases, whether from the point of view of humanity and philanthropy; of trade, commerce, mining industries, or other remunerative enterprises in which this country is now so actively and widely engaged; of military engagements; or of Christian missionary work. In this connexion I cannot refrain from calling attention to the intelligent, far-seeing, disinterested, and truly patriotic efforts made by our distinguished countryman, Sir Alfred L. Jones, a native of Carmarthen, to promote the study of tropical complaints on the spot, as well as at the Liverpool School of Tropical Medicine, and to do all in his power to endeavour to diminish their prevalence and gravity, or even to exterminate them altogether.

PRACTICAL ETIOLOGY.

I now proceed to deal briefly with certain points relating to what I may term the practical etiology of infectious diseases. With this aspect of the subject all members of the profession, whatever their position or sphere of work may be, are unavoidably and deeply concerned; and there is hardly any branch of medicine in which greater or more beneficent progress has been made, thanks mainly to those who have worked in the various departments of public health and who have taken an active interest in sanitation.

Now the first question to be determined from the point of view of practical etiology is whether a particular disease is infectious in the true sense of the term or not. As I have already remarked, some affections have been in modern times definitely proved to come under this category which previously could not be so regarded on any scientific grounds, of which tuberculosis is a conspicuous example. The dogmatic statements made on this point about other diseases which seem to be undoubtedly infective, such as pneumonia and rheumatic fever, must, however, be received with caution until further and more extensive inquiry has been made, though in the meantime it may be well to regard them provisionally as infectious in certain circumstances and to act accordingly. At the same time we should not ignore or forget the ordinary causes which long experience has taught us are capable of exciting these diseases, such as chill produced in various ways.

In the next place, it is very desirable, with regard to each individual infectious disease, to have as definite a knowledge as possible concerning its period of incubation, the degree of infectiousness, and the period of infectivity—that is, how long infection lasts in a particular case. In relation to many of the best known affections belonging to this group these points have been now established fairly accurately, but there is still much to be done in this direction. As regards the degree of infectiousness, undoubtedly the gradations in this respect between different diseases are by no means so clearly recognised as they ought to be, even by the profession sometimes, but more especially by the laity, and consequently one cannot help being struck with the want of proportion and tendency to exaggeration exhibited in the way in which certain of these complaints are dealt with. For instance, pulmonary tuberculosis is really nowadays looked upon by the large majority of persons as if it were a most virulent infectious disease, equal to small-pox or scarlet fever, which is, of course, absurd, but the idea has none the less got a firm grip and is doing an infinite deal of serious harm in different ways.

The most important and striking advance which has been made in relation to the practical etiology of infectious diseases is in our knowledge of the sources, modes, and channels of infection, both generally and with reference to individual members of the group; of personal predisposing conditions; and of the external circumstances which favour or promote their endemic and epidemic prevalence. On these matters our information was, within my own recollection, extremely vague and indefinite and many most significant facts with which we are now quite familiar were utterly unknown and even unsuspected, except by a few intelligent observers and earnest workers.

The question of the communicability of certain infectious complaints from person to person through the atmosphere is an extremely important one, especially when a number of individuals are aggregated together, as well as the distance to which the contagium can be thus conveyed and the agencies which assist in its dissemination. This question is by no means settled in not a few instances. Let me refer more particularly to typhoid fever and small-pox. While typhus fever has always been regarded as a disease strongly infectious from person to person, typhoid fever has been practically dealt with by the large majority of the profession as being free from danger in this way. Now, however, the tendency undoubtedly is, and probably rightly, to be much more careful as regards enteric fever from this aspect, and there is a growing objection to the admission of patients suffering from this complaint into the ordinary wards of general hospitals. Small-pox is still more important. Of course, it is a fact familiar to all that this complaint is highly infectious through the atmosphere, but how far it can be thus carried, particularly from a small-pox hospital or hospital ship and the influence of winds in conveying the infective agent, is another matter and may involve troublesome or even momentous consequences. I have noticed in the medical press recently directly contrary opinions on this question expressed by those who apparently have had equal experience and opportunities of arriving at a practical conclusion. How far emanations from drains, sewers, defective water-closets, and the like can produce so-called "blood poisoning" and other indefinite infective conditions is another question which needs clearing up.

Passing now to the more practical results of modern investigations as to infection the following facts are worthy of special attention.

1. As a starting point infective micro-organisms have been found and demonstrated in the blood; in certain secretions; in the excreta, urine as well as fæces; in the cutaneous structures or shed epithelium; possibly in the expired air; and in specific lesions, morbid products, and discharges from the body of various kinds. Hence we can readily understand how and why most of the diseases with which these organisms are associated are likely to be transmitted from individual to individual; how the infected materials may contaminate fomites and be thus conveyed far and wide; how they retain their activity in a dried state for an indefinite period, thus rendering apartments or other places infectious; and how they may be "air-borne," being carried about by atmospheric currents or winds and afterwards either inhaled or swallowed by persons, it may be, far removed from the original source of infection, remote epidemics being thus not uncommonly originated.

2. The communicability of certain grave diseases by the contamination of drinking water in different ways, but especially by admixture of infected excreta, is an established fact the importance and far-reaching consequences of which it is impossible to estimate or to realise in any adequate degree. Why such contamination should take place is often obvious enough, but it is rather startling to be told, as we have been within a recent period, that unsuspected and most inviting "spring water" may be a highly dangerous source of enteric fever. I have a very vivid recollection of an epidemic of cholera and another of enteric fever in Carmarthen when I was an apprentice, and in the light of modern knowledge there can be no doubt but that they were the result of infection through an excellent "spring water" in common use which had become contaminated with the specific excreta. While we are now all so familiar with the dangers of infected water, it required some hard teaching to convince the profession and the laity of its reality and we ought never to forget the excellent work done by Snow-Beck, Ballard, and other pioneers in relation to this matter. Even at the present time, moreover, my experience has led me to the conclusion that these dangers are by no means always appreciated as they ought to be, and I have met with not a few glaring instances of the injurious effects of ignorance or carelessness. In this connexion I may refer for a moment to the vigorous and praiseworthy efforts of my former pupil and friend Dr. H. E. Leigh Canney, who at any rate is fully alive to the evils and risks of water infection, to establish a Royal Water Corps as a special section of the Royal Army Medical Corps, the functions of which would be to prevent enteric fever, dysentery, cholera, and diarrhœa. It does not look, however, as if his project had "caught on" with the governing bodies and no doubt there would be serious practical difficulties in carrying it out.

3. One of the most striking additions in modern times to our knowledge regarding the conveyance of infection is in relation to food. In this connexion milk and its products stand out very prominently, not only on account of their frequent contamination by infectious materials, probably mainly from the deliberate addition of tainted water to milk, but also because this valuable food may convey organisms directly from diseased animals by which it is secreted. No doubt you are all familiar with the present controversy as to the communicability of bovine tuberculosis to the human subject in this way, but, notwithstanding Koch's dogmatic negative statement, more recent investigations, prominent amongst them those of Professor D. J. Hamilton of Aberdeen and Mr. M'Laughlan Young in this country, seem to have demonstrated conclusively that this authority, in spite of his high scientific claims and standing, is entirely wrong. At any rate, it would be a grave mistake to act on Koch's view or to ignore in the slightest degree the possibility of the conveyance by milk of the infective agents of tuberculous or other diseases. I will merely allude in passing to the probable danger in some cases of infection through meat, fried fish, uncooked vegetables, or various foods accidentally contaminated, as from being kept in infected rooms, or it may be by winds carrying organisms from a distance. But what shall I say about shell-fish? Dare I whisper in this neighbourhood the word "oysters"! Unfortunately there can be no doubt but that these "luxuries" are not uncommonly potent agents in originating enteric fever, and the same statement applies to the more humble and democratic mussels, cockles, or even periwinkles, as well as possibly to lobsters, crabs, and the like. May I venture to suggest that it is extremely desirable for all concerned that everywhere the utmost precautions should be taken to prevent as far as possible these most desirable and valuable articles of food from being contaminated by sewage of any kind, and the deliberate feeding of oysters on such materials, for commercial purposes, cannot be too strongly condemned and ought to be put a stop to by the most stringent legal measures.

4. The rôle which different animals play in the transmission of infectious diseases to man is another aspect of the subject upon which modern observations and researches have thrown remarkable light. Of course the relationship in this respect of such diseases as hydrophobia and glanders has long been recognised. The idea of direct infection through the milk or flesh of infected animals is of comparatively recent date. The danger of infection being carried directly by domestic animals, such as birds, cats, and dogs, from person to person, or perhaps because they themselves are suffering from certain diseases, is not yet appreciated as it ought to be. The rôle played by such unwelcome "large vermin" as rats and mice in relation to plague, and probably some other complaints, is now familiar to all. Flies, cockroaches, and the smaller but too well-known personal vermin may no doubt be instrumental in conveying infection in certain cases, and flies may thus taint food. But the most remarkable and important revelations which modern investigators have given us as to the transmission of infection by animals are those relating to mosquitoes. The discovery and demonstration of the connexion between these minute torturers of humanity and malaria, in which Sir Patrick Manson and Major Ronald Ross have taken such a prominent part, has already worked incalculable good and promises in the future to revolutionise the conditions of life in many parts of the world, to the inestimable advantage of the

communities who are native to the district as well as of Europeans whom circumstances compel to reside there. The same statement applies to yellow fever and probably to other affections prevailing in climates and localities where mosquitoes abound.

5. The question of the relation of infection to soil, place, and particular houses or groups of houses is a very important one, but about which there is at present much that is uncertain and indefinite, and that needs to be worked out more fully before any positive conclusions can be arrived at with regard to individual diseases. The fact that the tetanus bacillus comes from the soil, being especially associated with garden earth or horse-dung, is well established and was a most interesting and important modern discovery. Beri-beri is regarded by Manson as a "place disease," due to a toxin produced by a living germ operating in some culture medium outside the body. Of course, houses or rooms may, when once infected with the organisms of well-known diseases, retain them indefinitely and thus be the means of originating similar affections after long intervals.

6. Another most important aspect of infection from a practical point of view is the fact that we are every one of us always carrying about in various parts of our bodies microbes which, while habitually innocuous and non-virulent, may under favouring conditions, so far as they are concerned, become extremely virulent, or possibly specific, to our personal undoing; or we may even be harbouring in our mouths, throats, noses, ears, and thereabouts specific germs by which, quite unintentionally, we are liable to infect others at any time while we ourselves go scot-free. It is certain that very dangerous germs may lie dormant for an indefinite period in the human body, such as the bacilli of diphtheria, influenza, or tubercle, or their spores, and either lead to unexpected auto-infection or to the corresponding specific disease in others. When suppuration is set up in any part of the body, moreover, it is wonderful how disagreeable the different organisms can be in the way of migrating to various other structures and producing a similar condition in connexion with them.

7. I must just refer, lastly, to the progress made in our knowledge of the channels of entrance of microbes into the system and the modes in which they are disseminated. Here again the mouth, the throat, and the neighbouring parts come into unpleasant prominence, especially the tonsils, in connexion with scarlet fever, rheumatic fever, tuberculosis, actinomycosis, and other diseases. The dissemination of the organisms by cells, the blood stream, and the lymphatic channels is also an important fact positively demonstrated and in this dissemination embolism not uncommonly plays a conspicuous part.

MORBID ANATOMY AND HISTOLOGY.

I can only touch very superficially on this aspect of my subject, in order to draw attention to two or three of the more important points. Our knowledge of the actual nature and characters of the specific pathological lesions of most of the infectious diseases, both macroscopic and microscopic, has, I need hardly say, made enormous strides and much of it is in reality, for obvious reasons, of quite modern discovery and demonstration. Further, the recognition of the fact that certain pathological manifestations in connexion with internal organs or other structures are an essential part of an infective disease and not merely accidental complications or sequelæ, as was formerly supposed, if they were recognised at all, is an important step in advance. This may be exemplified by the relationship of renal disease to scarlet fever and of cardiac inflammations to the rheumatic state. At the same time our knowledge of what may be fairly regarded as complications and sequelæ of this class of complaints has not only greatly increased but has become much more definite and intelligible. As important pathological factors which are particularly liable to bring about complications and sequelæ in infective diseases may be mentioned congestion, inflammation, suppuration, embolism or thrombosis, and acute degenerations.

The last point I would refer to in this connexion is the very striking and most valuable results which have been derived from experimental investigations on animals with regard to the pathological effects of different pathogenic microbes and their toxins and more especially in relation to the nervous system. These have a direct bearing on the nervous sequelæ which so often follow several of the infectious diseases and which have come so prominently before the profession during recent years.

CLINICAL HISTORY AND PHENOMENA; DIAGNOSIS.

While we have to record certain distinct advances in knowledge of the clinical history of several of the infec diseases, and while important additions have been made our means of diagnosis, to which I shall presently refe cannot be said, speaking broadly, that the progress in direction has been anything like commensurate with relating to their pathology and etiology. Of course we better acquainted clinically with such diseases as ent fever, diphtheria, influenza, and tropical fevers because have become more familiar to the profession generally, modern knowledge enables us to understand and to expl more clearly their clinical phenomena on a patholog basis. Moreover, now and then careful observation reveal new symptom or class of symptoms which proves to be conspicuous diagnostic significance, as in the case of "prodromal exanthems" of small-pox and Koplik's "buc spots," which seem to be of real value in the early recog tion of measles.

I presume it will be acknowledged on all hands that early and correct a diagnosis as possible is of the utm importance in the case of the several infectious disea which come under observation in the ordinary routine medical practice. This is of special moment when deal with numbers of individuals brought into more or less timate association; and I mention schools as a promine and constant source of anxiety and worry to all concern in relation to these complaints. Now it must be insist upon at the outset that such diagnosis is in the lar majority of instances actually and positively founded very simple data, easily observed and readily studied that is to say, we must as a matter of general rout rely, and can safely rely, in the diagnosis of a partic infectious disease, as regards its actual clinical history, its mode of onset or invasion, its course or progress, a the simpler phenomena which personally I always speak as "symptoms," as distinguished from those revealed b skilled physical or other special methods of investigatio And, in my opinion, it would be a serious mistake encourage in any way the idea that in the ordinary run cases of this class of complaints we cannot come to a definite conclusion except with the aid of modern scienti methods. Under the category of symptoms it must be note that subjective morbid sensations, either general or local, a very conspicuous and significant in several diseases of a infectious nature. But, of course, it is from objectiv symptoms which we can ourselves note and investigate tha we derive our chief and more trustworthy information. The may be evident or attract attention at once and one or mo may be even quite pathognomonic, such as the peculia cough of pertussis or the nervous and muscular disorders characteristic of tetanus and hydrophobia. The cutaneous eruptions or rashes of the exanthemata constitute a most important group of objective symptoms with which it is essential to be thoroughly conversant in all their details. The external manifestations of such infectious diseases as mumps, syphilis, plague, anthrax, and glanders also come under this category. So-called catarrhal and throat symptoms are of common occurrence and the affected parts can, as a rule, be easily seen or felt; while such a disease as gonorrhœa is recognised by its specific urethral discharge. The phenomena associated with the well-known internal lesions of such diseases as typhoid fever or dysentery are, as a rule, very significant or even characteristic. Of course, such affections as pneumonia or rheumatic fever, which are now classed among the acute specific fevers, as well as tuberculous affections will have their own peculiar localising symptoms.

There are certain general symptoms which, in a large proportion of infectious and infective diseases and cases, demand careful observation and study. Those indicative of the "febrile state," I need scarcely say, often assume a special prominence. From this point of view I presume that every medical man, as a matter of routine, "feels the pulse," "looks at the tongue," and "takes the temperature." In some instances both the pulse and the tongue afford special information, but I am not at all sure that this fact is always duly appreciated nowadays. In this connexion one can scarcely avoid making some allusion to the "clinical thermometer." This small instrument is, I need hardly remind you, at present universally recognised as an invaluable and often essential aid in diagnosis in most infective diseases, not only in determining the existence of pyrexia, but also in studying its degree, course, and other details. Quite recently there was an interesting correspondence in

British Medical Journal concerning the history of the thermometer for clinical purposes, to which I may be permitted briefly to refer. In the issue of April 4th Sir William Broadbent brought forward the historical fact that an army surgeon, Dr. Archibald Arnott, recorded the temperature in the case of the First Napoleon at St. Helena in 1821. He says that the record is set down as if it were a regular part of routine observation and Dr. Arnott must have had a thermometer with him for the purpose. In attempting to trace back how Dr. Arnott came to adopt the nstrument he thinks it probable that he learnt its use n the wards of the Edinburgh Royal Infirmary. He calls attention to the fact that Dr. James Currie, of Liverpool, whose first edition of his work on "*Cold Affusion in Fever*" was published in 1797, was an Edinburgh graduate and was irst led to employ the thermometer by a debate at a society of students there. Sir William Broadbent's interesting statement led to further communications, showing that the bodily emperature was systematically recorded in febrile diseases by several observers during the latter half of the eighteenth and first half of the last century, amongst them by Dr. Livingstone, in Africa, in 1853. As is well known, however, t is to the observations and writings of Wunderlich, about he year 1860 and subsequently, that we owe the general recognition of the value of clinical thermometry. Sir Samuel Wilks states that he was led to procure an instrument for Guy's Hospital by reading the chapter on the subject in Aitken's "Practice of Medicine." He thus describes it: "I think it was nearly a foot long and was so great a novelty that it was taken to a South-eastern meeting of the British Medical Association for exhibition, where the members regarded it with much curiosity and interest, although, I am sorry to say, one or two with ridicule." What a contrast to the neat and convenient, easily applied, very rapid, and most accurate recorder of bodily temperature now at our command.

I have thus dealt with the symptomatic aspect of infectious diseases somewhat at length—in the first place, because I regard it as of fundamental and essential importance in the ordinary run of cases, notwithstanding the progress made in scientific clinical methods; and secondly, as a protest against the tendency amongst the rising generations of our profession, which it is impossible to overlook, either to ignore common symptoms altogether, as if beneath their notice, or to take no trouble whatever either to understand or to study them. I would remind them that their predecessors—not so very long ago either—had no other data upon which to found their diagnosis, and practically no scientific instruments or apparatus to help them, and yet most of them knew pretty well what they were about. In relation to the complaints with which we are now concerned, it is usually a combination of symptoms which are of diagnostic significance; and in many instances they are more or less characteristic even during the so-called "premonitory" stage, though they usually become more definite later, and it may be impossible for a time to arrive at a positive opinion. As already stated, in some of these diseases one particular symptom or class of symptoms is, however, quite pathognomonic.

I now pass on to refer briefly to other modes of investigation not uncommonly of much diagnostic value in relation to infectious and infective diseases, which are also comparatively easily practised and are supposed to be carried out more or less as a matter of routine in ordinary medical practice. I allude to physical examination, especially as applied to the chest and abdomen; and examination of the urine. Of course, in the clinical study of many inflammatory diseases and special affections now included under this category—for example, pneumonia or cardiac rheumatic manifestations—skilled physical examination is essential, while it is also of great help in the detection of complications and sequelæ, to which it must be noted attention may not be attracted by any prominent symptoms, and consequently they are very liable to be overlooked unless the practitioner is constantly on the alert to detect them by the systematic employment of this method of investigation. The necessity for examining the urine at frequent intervals would, I suppose, be generally recognised in scarlet fever, or perhaps even in diphtheria, for well-known reasons; but this measure is not always carried out so regularly or systematically as it might be in other complaints of an infectious nature. As a special test applied to urine I may remind you of Ehrlich's "diazo-reaction" for typhoid fever; but it is not trustworthy, even when present, as it may be met with in other affections.

The special methods of diagnosis applicable to infective and infectious diseases which modern scientific researches have brought so prominently before the medical profession have naturally attracted great attention and excited keen interest. It might be thought an occasion like this would afford a most suitable opportunity for discussing these methods at some length and endeavouring to estimate their practical advantages up to the present time and their future possibilities. I have preferred, however, to devote most of the time I could give to the clinical aspect of my subject to the more common modes of investigation, for reasons already sufficiently indicated. I have therefore left myself but little space to deal with these more scientific methods which I may remind you often require the help of an expert before their results can be safely relied on. I shall content myself with merely giving the following summary of these methods and their objects, mainly coming under the head of bacteriological diagnosis. They include: 1. Examination of the blood, both as regards its normal constituents, especially the number of leucocytes and the relative proportion of different kinds of cells, the blood plates, and the presence of abnormal corpuscles, and from a bacteriological point of view. The spirillum of relapsing fever and the malarial parasites are prominent examples of pathogenic organisms found in the blood and the latter have to be observed and studied during the changes they undergo, along with their effects upon the red corpuscles and the formation of pigment. 2. The further detection and microscopic demonstration of organisms, specific or non-specific or both, either obtained from the tissues of the body or contained in secretions, fæces and urine, various discharges, sputum being particularly noteworthy, and other morbid products of different kinds, fluid or solid, of which diphtheritic material is a conspicuous example. The organisms are not only identified by their morphological characters but also as a rule by their peculiar staining reactions. 3. Separation or isolation of the microbes, which are afterwards grown on suitable media in order to obtain cultures, the results being often highly characteristic, both to the naked eye and on microscopic examination. 4. Application of the "segregation" and "agglutination" tests in relation to the blood serum of the patient, which is most familiar to us in Widal's test for enteric fever. 5. The observation of the effects on the individual of the inoculation of certain products of the specific microbe of the disease from which he is supposed to be suffering, as in the so-called "reaction test" with tuberculin for tuberculosis. 6. The pathological results of inoculation of animals, either with the organisms themselves or with their toxins, which in some instances are essential for positive and accurate diagnosis, lesions of a definite and characteristic nature being thus produced, as is well exemplified by diphtheria.

A rather awkward question, but one of extreme practical importance to the profession, has been recently forced upon our notice which I cannot altogether pass by. In the *British Medical Journal* of March 7th an abstract is given of a disquieting statement issued by the Hospitals Committee of the Metropolitan Asylums Board as to the numbers of cases of mistaken diagnosis sent to the hospitals of the Board as notifiable during the three years 1899-1901. The subject is very ably, fairly, and sensibly dealt with in a leading article in the same journal of March 14th on the Diagnosis of Notifiable Diseases, which might be read with advantage by all who are directly interested in the question, or indeed even by the laity generally. They do not in the least realise the difficulties which confront the practitioner, with whom I have the deepest sympathy; and residents at the infectious hospitals cannot be too careful and particular not to hurt the feelings of their brethren in the profession more than can be possibly helped. Of course, any carelessness in diagnosis in relation to infectious diseases is inexcusable, but really young practitioners are not responsible for the fact that they are not so familiar with these complaints clinically as would be desirable and that many of them have to gain the requisite experience after they have entered upon their active professional duties. May I venture to suggest that while the modern medical student has immense advantages he labours under a decided disadvantage from this point of view, as compared with those of us who served an apprenticeship and became familiar with, at any rate, the more common infectious diseases, even before we started upon our regular studies at a medical school. As a matter of fact, he gets very little opportunity of gaining practical knowledge of most of these complaints during his period of studentship and has to fall back upon so-called "post-graduate instruction" if he desires further and more special training and experience. The bacteriological methods of diagnosis ought to help materially, should there be any real difficulty, in diminishing the number of mistaken cases in the future, especially if facilities are afforded to the practitioner of using them without delay, but they are not infallible, even where they can be applied.

TREATMENT AND PREVENTION.

To the laity of course the question which appeals most directly and pressingly with reference to infective and infectious diseases is, What position do we as a profession stand in to-day as regards their treatment and prevention? Have we made any progress at all; and, if so, to what extent and in what directions? Have we fulfilled the somewhat optimistic forecasts and promises which have been so frequently and loudly expressed in speech and written article during recent years.

In the first place, it must be admitted that we can boast of but very few "specific remedies" added to our list for the treatment of individual infective or infectious diseases in modern times, though we understand far better the modes of action of several of those which were used previously on empirical grounds, as you, Mr. President, have pointed out in your Address. Indeed, beyond the employment of salicin and salicylates or allied agents for rheumatism, I am not sure that we can claim any positive and assured discovery of this kind. Of course, there are not a few practitioners who have a routine treatment or a particular remedy for each one of these complaints, in which they implicitly believe, and which is infallible according to their own account. I must, however, much to my regret, while envying their "cocksuredness," decline to accept their statement as gospel. In my opinion, speaking generally, the more of an "open mind" and a "free hand" the practitioner cultivates in dealing with the majority of infectious diseases the better will it be for his patients.

Taking a comprehensive survey of the changes and modifications which have taken place in the treatment of infectious diseases one of the most conspicuous and beneficial is that the severe depleting and depressing measures which were formerly extensively if not almost universally carried out have been practically done away with and are now only resorted to in exceptional circumstances or for particular purposes, as in the free use of purgatives for certain individual complaints. Further, it is a profound matter of congratulation for ourselves and our patients that we now apply practical common sense and sound physiological, natural, and sanitary principles in dealing with these diseases as a matter of routine, in the way of physical and mental rest, abundance of fresh air and free ventilation, careful attention to hygienic conditions and surroundings, regulation of diet, personal cleanliness, general comfort, judicious disinfection, and other essential matters. In this connexion we can never forget or ignore the immense advances which have been made in the science and art of nursing and it would be impossible to over-estimate the service and help which the "trained nurse" can, and as a rule does, render in dealing with cases of infectious diseases in many trying and anxious circumstances. In my opinion a very large proportion of cases of acute specific fevers can be steered through their course on the lines just indicated without any active treatment whatever unless it be an occasional aperient; or if the exigencies of private practice demand some "medicine" we have excellent friends in the old-fashioned "saline mixture" and the "effervescent mixture," which at any rate are quite harmless and may be of definite use for certain purposes. The "open-air" treatment of phthisis is in reality in the main a mere development of similar principles.

Let it not be supposed, however, from what I have just said that I advocate a general policy of "masterly inactivity" in dealing with infectious diseases. Although we have but few novelties in the way of "specific remedies" to boast of, many most valuable medicinal agents in the treatment of these complaints have been introduced within comparatively recent times, whilst others previously known have also come to be employed with much advantage for certain definite purposes. There are many diseases and cases in which even from the outset the practitioner must recognise the necessity of administering in some way or other suitable medicinal remedies, or events not uncommonly supervene during their course which call for his interference, and he ought to know what to do in the particular circumstances and be prepared to act accordingly.

Without entering into any details I may point out that one of the chief classes of therapeutic agents which in modern times have come to the front in the treatment of infectious diseases are antiseptics, antiferments, germicides, or bactericides, as they are variously called, to which group not only many most valuable additions have been and are being made, but which are now employed in ways which our predecessors never dreamt of, though I think that some of the methods of using or administering certain antiseptics in relation to particular diseases which are advocated and practised at the present day are decidedly open to criticism. Another remarkable group are the antipyretics prepared in the chemical laboratory—phenazone, acetanilide, phenacetin, &c.—which when judiciously given may be of conspicuous service. Other agents deserving of mention are cardiac stimulants and tonics, strychnine being now recognised as a most valuable remedy from this point of view; and the newer hypnotics or other drugs intended to relieve particular symptoms, which may thus afford material assistance in guiding patients through serious illnesses of this nature. In this connexion I may also mention certain therapeutic methods and agents of comparatively modern introduction which are undoubtedly of conspicuous service in combating grave conditions immediately threatening life, such as subcutaneous or intravenous injection of ether or other diffusible stimulants, inhalation of oxygen, saline injections, and transfusion of blood or other suitable substitutes. For the various complications and sequelæ with which we have so often to deal in relation to infectious diseases and which not uncommonly sorely perplex us treatment must be conducted on general principles, guided by the knowledge, experience, and common sense of the practitioner.

There are certain special questions bearing upon the treatment of infectious diseases which I cannot pass over on an occasion like this without brief comment.

1. *Hydrotherapy and allied methods.*—No doubt you are aware that Dr. James Currie of Liverpool, to whom I have previously alluded, strongly advocated and carried out the treatment of fevers on a considerable scale by baths and douches. This treatment fell into practical desuetude, and, indeed, was generally looked upon with aversion and dread. In modern times, however, it has not only been revived but numerous other methods for applying cold to the body, either generally or locally, have been added, not only by means of water, but also of ice and cold air. These methods are now generally recognised and extensively adopted, probably more on the continent and in the United States of America than in this country, even in the treatment of many of the ordinary fevers, but especially in the more severe cases; and the local application of ice is strongly advocated in acute pneumonia and other inflammatory infective diseases. While of great value as antipyretics they have other important beneficial actions, which I need not now specify. Regarding hydrotherapy and allied measures in the treatment of infectious diseases, I would remark that every medical practitioner ought to be familiar with them and be able and ready to carry them out when required. The milder methods, such as sponging the skin or applying ice locally, are easily practised and are often of the greatest service. Personally, however, I do not advocate or employ the more severe methods as a routine system, as many do; and I feel sure that I have met with serious injurious consequences from such a practice. On the other hand, their essential value in saving life under grave conditions cannot be too strongly insisted upon.

2. *Use of alcohol.*—I now come to a question in relation to the treatment of infectious diseases and cases, both generally and individually, which demands the most thoughtful consideration—namely, that of the administration of alcohol. And I feel bound to take this opportunity of stating emphatically that when we, as members of the medical profession, approach from any point of view this alcohol question, we ought to do so under a deep sense of responsibility, but at the same time rationally and without undue bias one way or the other. At a large political meeting held not very long ago an eminent statesman was contrasting imperial with local questions and giving his own ideas about their relative importance, founded upon certain personal experiences. Amongst the local questions he mentioned "temperance reforms" and his allusion was received by the audience with "loud laughter." I venture to say that such is not the spirit in which this grave subject ought to be regarded at the present day by any community; and, at any rate, the medical profession as a body is bound to sympathise with and to encourage every effort made in this country to check the

terrible evils produced by intemperance, which confront us in such an overwhelming and appalling degree on all hands in our daily experience, and to do our utmost to promote sobriety amongst all classes, however hopeless the task may appear to be. And from this point of view we should always be most careful to avoid ordering stimulants to patients not accustomed to them unless they are, in our individual opinion, really necessary; while it is well always to give very definite instructions as to their administration. There is an influential body of the medical faculty in this and other countries, some of the members of which are of the highest professional and scientific standing, who absolutely and entirely object to the use of alcohol in any circumstances, and for these ladies and gentlemen I entertain the highest respect. As you are probably aware, an "International Medical Manifesto" against the use of alcoholic liquors was issued a short time ago, which roused resentment and a strong protest on the part of some members of our profession. To a certain extent I share their feelings, for, with all due respect to the opinions and statements expressed in that manifesto, I think those who signed it have gone too far and I regret that I cannot altogether agree with them. At any rate, so far as infectious diseases are concerned, I must express my own strong conviction that in a large number of cases the judicious administration of alcohol is of the greatest service, and I have seen a considerable number of grave, and sometimes almost hopeless, cases in which I have no hesitation in affirming that recovery was due to the use of alcoholic stimulants, not uncommonly in considerable quantities. Moreover, they are often of conspicuous value during convalescence. With ordinary prudence and care it is quite easy to avoid establishing a habit of taking stimulants in the case of patients who have been previously abstainers. While thus expressing my personal opinion in favour of the use of these agents in infectious diseases in suitable circumstances, I feel bound, on the other hand, to warn against their employment as a matter of routine, and I venture to urge that the most thoughtful and conscientious consideration should be given to every individual case before ordering them.

3. *External and local treatment.*—The treatment of external or local manifestations of particular infectious diseases, such as scarlet fever, small-pox, or diphtheria, affords legitimate ground for differences of opinion, and I must confess it is often puzzling to determine what is best to be done for such conditions when one reads the different methods of treatment advocated by different experienced authorities. I cannot refer to them further now and must content myself with saying that the measures to be adopted must be determined very much by the particular views of the practitioner, guided by judgment and discretion and modified by the special circumstances of each case. Antiseptics and disinfectants are employed with great advantage as local applications for various purposes. How far the light treatment, the x rays, or particular colour rays are going to help us, cannot be definitely determined at the present time. Just now the subject has come very prominently before the profession and the public, and the "red-light treatment of small-pox," which, however, is by no means a novelty, so strongly advocated by Professor Finsen in the *British Medical Journal* of June 6th, is attracting special attention, as well as some adverse criticism. What we may expect, also, from that wonderful newly discovered element—radium—it is impossible to foretell, but we must be on our guard against accepting statements as to its marvellous curative effects by irresponsible observers.

4. *Vaccines: Serum-therapy.*—What would, no doubt, be generally regarded as the most vitally interesting and important question of modern times, bearing upon the prevention and treatment of the entire group of infective diseases, is that of "serum therapy," using the term as an inclusive one which has come as the natural outcome of the microbic theory and is founded, on the whole, on reliable bacteriological researches and experiments, supported by the results of practical experience in living subjects. Time will only permit me on the present occasion to touch the fringe of this most attractive and fascinating subject, and I will merely ask you to bear with me while I remind you for a moment of what this method of treatment consists, and what are its objects and aims. Following Sims Woodhead's classification, the materials used are divided into—(1) vaccines, which are either cultivations containing pathogenetic micro-organisms with toxins or toxins only, or the tissues or fluids of an animal suffering from a particular infectious disease; and (2) antisera, which may be antitoxic only, neutralising the toxins, antibacterial or antimicrobic, acting directly upon the organisms, or in some instances having both actions. The comparatively recent investigations of Professor A. Macfadyen and Mr. Sidney Rowland with regard to the immunising power of the cell plasma of the typhoid bacillus, and the effects of repeated injections of this substance in rendering the blood serum of an animal both antitoxic and bactericidal are very remarkable and promise great results in the future. Up to the present time these therapeutic agents have been practically only employed by inoculation, being usually injected subcutaneously, but exceptionally more deeply, or into special structures. I note, however, that the antidiphtheritic serum has lately been recommended to be administered by enema, or even in pastils. Vaccines and antisera are employed either for the purpose of producing temporary or permanent immunity against an individual disease; or for the actual treatment of certain complaints or morbid conditions, either acting as definite "cures" or so modifying their course that their severity and dangers are materially lessened, their progress is hastened, and their mortality is greatly diminished. The large majority of these agents are specific, being only used in relation to a particular disease, but the antistreptococcic serum has been found of service in various affections and so-called "Coley's fluid" is also non-specific. The diseases thus treated with which we are most familiar are small-pox, as prevented or modified by vaccination and revaccination, hydrophobia, diphtheria, tetanus, enteric fever, scarlet fever, cholera, pneumonia, septicæmia, anthrax and glanders, plague, tuberculosis, leprosy, and cancerous or sarcomatous growths, assuming them to be infective. Now no one who has watched the course of events during recent years and who is unprejudiced can doubt for a moment or fail to acknowledge the immense value of this modern therapeutic method in relation to some of these complaints. There are others, however, in which thus far it has entirely failed in its objects, while in others still it is on its trial and those who are in a position to speak authoritatively differ widely in their views and conclusions as to its efficacy in some of the most important infectious diseases. Personally I confess that I am inclined to regard not a few of the positive statements made with a sceptical mind and I think we ought to be particularly careful in accepting and acting upon them at the present time, remembering the suspicious and not too friendly attitude of a large number of the influential laity towards the medical profession. At the same time it cannot be too strongly insisted upon that every member of the medical profession ought to avail himself or herself to the full of any method of treatment which bacteriology offers us, provided it has been scientifically and practically proved and demonstrated to deserve our confidence. It is not for us, in the present state of the law, to deal with the "conscientious objector," but I emphatically affirm that any individual practitioner who wilfully and with intent neglects or is in actual antagonism to vaccination and revaccination as a protection against small-pox may be justly regarded as guilty of a grave dereliction of duty and is responsible for serious mischief, the results of which are but too evident to any unprejudiced observer. The same remark certainly applies to the neglect of the vaccine or antitoxin treatment for diphtheria, hydrophobia, tetanus, and anthrax. The opening of the new buildings of the Jenner (now the Lister) Institute of Preventive Medicine encourages the hope that this country will not in the future be behind others in advancing this most important and promising branch of scientific and practical medicine.

It was my original intention to offer some observations on the prevention of infectious diseases from a general standpoint, but I have already trespassed too long upon your patience and must content myself with a few closing remarks. I venture to affirm that the predominant aim of the medical profession as a whole is essentially beneficent. In support of which statement I can confidently draw attention to the deep interest exhibited by its members in this question and to the efforts made by them, not only to limit and to prevent these complaints in a general way, but to eradicate and to exterminate those with which we may be thus able to cope effectually. This is no sham or pretence on our part, but an honest and straightforward policy and purpose to which not a few devote their lives and best efforts, which ought to be a rebuke to scoffers and slanderers, of whom there are many. I will go further and say that in dealing with infectious diseases medical practitioners and scientific workers often exhibit a brave, courageous, and self-sacrificing spirit which is worthy of our highest esteem and admiration. To go into the midst of a virulent epidemic and to fight against it day and night, often under the most trying and adverse conditions, which is no uncommon experience, is no trifling matter; and I could give many instances of individual courage and devotion, as well as of voluntary exposure to grave personal danger, sometimes ending fatally, which were truly heroic. Even the bacteriological researches in laboratories, which are intended to benefit humanity, are a source of danger—witness the cases of fatal infection with tuberculosis and the death of the young Austrian medical man who not long ago succumbed to plague while working in Berlin. But I feel bound to pay a special tribute of respect and admiration to those who have gone forth to pestilential climates and often under great hardships, or even by submitting themselves to dangerous personal experiments, have done such marvellous work in diminishing and controlling, or in some districts even exterminating, malarial and other diseases which were formerly the cause of destruction of human life on a vast scale, as well of such extensive and profound deterioration of health.

What will be the future progress of events in relation to the prevention of infectious diseases it is impossible to foretell or to estimate, though the forecast is in certain directions decidedly hopeful. I venture, however, to submit that we as a profession should be extremely cautious as to what we say and should avoid a too "cheery optimism" in the way of making promises and predictions which, recognising the very nature of things, the conditions under which humanity exists, and the difficulties which so-called civilisation brings with it, experience and common sense must tell us are, to say the least, extremely rash. On the other hand, let us never relax in our efforts to promote the good cause and to encourage, to develop, and to enforce every measure, scientific or practical, which has for its object the mitigation or prevention of those widely spread and often terrible infectious diseases which now add so enormously to the death-rate and which, even in cases of recovery, leave such serious after consequences amongst large numbers of the community. And this we must do in spite of opposition, however powerful, persistent calumny, vicious attacks on our motives, or even being called foul names. There are numerous "antis" about just now, but for downright insolence and impudence the anti-vivisectionists "hold the field." They have the most astounding faculty and capacity for fabricating statements for which there is absolutely no foundation, for distorting facts, and for cooking statistics, and they stick at nothing. Let us treat them and their hysterical outbursts with the contempt which they deserve. Our duty is plain enough. Not only must we work on steadily as a profession in the direction I have indicated but we must earnestly strive to gain the confidence and coöperation of influential individuals and communities and to guide them on intelligent and rational lines.

I have been asked to speak in this address in support of the appointment of a Minister of Public Health. I note that you, Mr. President, are not in favour of such an appointment, but personally I really do not feel competent to speak one way or the other. You have sketched a scheme with regard to the practical and official working of the Public Health Department which appears to have sound principles underlying it, and at any rate some change is obviously necessary. In the meantime, however, we must do what we can to educate and to influence borough and county councils and other public bodies which are concerned with sanitary matters, as well as members of both Houses of Parliament, and to stimulate them to do their duty. Thus will we, as members of a self-sacrificing and noble calling, while endeavouring in our individual capacity to perform conscientiously and intelligently the duties which devolve upon us in relation to actual cases of infectious diseases which come before us in our several spheres of practice, be further, collectively and with concerted action, doing what lies in our power to promote the health and wellbeing of our fellow creatures on a large and comprehensive scale and to avert or to mitigate the effects of those grave maladies which are now such a scourge to humanity.

UNIVERSITY OF ABERDEEN.—After the graduation ceremony on July 24th a bronze tablet, to the memory of the late H. Alleyne Nicholson, M.D., D.Sc., F.R.S., professor of natural history in Aberdeen University, was handed over to the custody of the University authorities by Professor Arthur Thomson, on behalf of the subscribers, who numbered about 60 of the friends, colleagues, and students of the late professor.

Address in Surgery:

OBSERVATIONS ON THE EVOLUTION OF ABDOMINAL SURGERY FROM PERSONAL REMINISCENCES EXTENDING OVER A THIRD OF A CENTURY AND THE PERFORMANCE OF 2000 OPERATIONS.

Delivered at the Annual Meeting of the British Medical Association at Swansea on July 30th, 1903,

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,
HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. PRESIDENT AND GENTLEMEN,—I know well that to be invited to deliver the Address in Surgery before the British Medical Association is to receive one of the greatest compliments that the profession can confer, for the council represents a unique constituency, both in numbers and intellect. But with the sense of honour comes also the profound sense of responsibility, hence it was with mingled feelings that I ventured to accept your kind invitation. A third of a century has elapsed since I entered on my medical work and when I look back over that long period and see the changes that have occurred I am inclined to wonder whether I really belong to the same profession as in 1870. It was then quite usual for the surgeon to be physician, obstetrician, and general practitioner at the same time, and only in a very few of the large centres was surgery made a specialty of; yet such have been the increase of knowledge and the improvement in technique in the art and science of surgery in its various branches that the extinction of the general surgeon at one time appeared possible, which would have been a misfortune; for although thoroughly believing in specialisation, I consider that the specialty should come later; in other words, I would have the surgeon first to know something of everything in his profession and later everything of something, since we must all acknowledge that the accumulation of knowledge renders it impossible that one should know all of everything. Along with many of my audience I have had the advantage of witnessing the revolution not only in surgery and medicine but in every branch of medical work, which occurred during the last 30 years of the nineteenth century, such changes as will stamp that period for ever in the annals of our art. The surgeon who entered on his work in the "eighties" or later can scarcely picture to himself the state of affairs that existed in the early "seventies," when it was possible to see, as I myself have done, a hospital ravaged with hospital gangrene and phagedæna; when erysipelas, pyæmia, and septicæmia were never long absent from any surgical wards; when any operation, however simple, might assume complications of the most serious import; when secondary hæmorrhage was of frequent occurrence; when compound fractures often took months to heal and frequently ended in loss of life or limb; when erysipelas was put down to change of weather, tetanus to nerve irritation, tubercle to a diathesis, and rapid deaths from septicæmia to shock. Those of my hearers who have passed through this period of the history of medicine have witnessed the birth and growth of the science of bacteriology and the nativity, infancy, adolescence, and sturdy manhood of its brilliant offspring, antiseptic and aseptic surgery, the distinguished author of which, I am glad to say, is still with us and has himself witnessed the truth of his theories and the success of his system in the saving of more lives each year than Napoleon destroyed in all his wars. It is clearly impossible in a short time even to record briefly all the advances made in surgery, but in my work as a general surgeon I have also had the privilege of taking part in the development and progress of a special branch—abdominal surgery—than which nothing could better exemplify the great changes that have occurred during the 33 years which I am considering, for in the early "seventies" abdominal diseases were practically always treated expectantly, and if we look at the reports of 1870 we shall see that, as judged by results, it was perhaps just as well that surgery had then no business inside the abdomen

As knowledge increased [illegible] tific, many of the diseases [illegible] from the beginning or at a [illegible] so that to day abdominal surgery is a subject of the first importance Not only has treatment advanced by leaps and bounds but our knowledge of abdominal diseases and their successful diagnosis has enormously increased, partly by pathological advancement generally and by experimental research but also by philosophical observations on the operating table and the study of disease in the living subject, in other words through biopsy instead of necropsy The time was when the physician thought he had done all that was necessary when he had arrived at a probable diagnosis and he philosophically waited until his hypotheses were proved or disproved in the deadhouse; treatment was left to the junior as being quite a secondary matter and I am bound to say that in abdominal diseases that were not merely functional and that could not be treated in the out-patient department the estimate placed on treatment was often correct Then ovarian disease was generally known as a form of dropsy and was either treated by tapping, when the pressure became so severe as to demand some relief, or seeing that tapping was at times fatal or only gave a temporary respite, the greater number of cases went untreated The surgery of the intestines, except for strangulated hernia, was not thought of and uterine, renal, gall bladder, stomach, liver, and pancreatic surgery was hardly dreamt of as possible In 1870 an attempt was being made in some of the general hospitals to emulate the example set by certain pioneers, such as Clay of Manchester, Spencer Wells of London, and Keith of Edinburgh, but with what result? It is interesting to note the following facts In St Bartholomew's Hospital in 1870 there were three ovariotomies, all fatal, and 20 cases of herniotomy in which the sac was opened, with nine deaths In Guy's Hospital there were five ovariotomies, with three deaths, and 19 herniotomies with opening of the sac, with 11 deaths In St. Thomas's Hospital there was one ovariotomy, in which death occurred, and there were 14 herniotomies, with eight deaths In St. George's Hospital there were two ovariotomies, both ending fatally, one colotomy, which ended fatally, and 20 herniotomies, with eight deaths In the same reports there was always found a special record of the number of cases which are now so rarely seen For instance, in one of the reports for 1870 there were recorded 53 cases of erysipelas, 20 of phagedæna, 93 of diffuse cellulitis, and four cases of secondary hæmorrhage after operation, which at the present time would be sufficient to condemn any surgical clinic, yet this record was no exception, as all the hospitals furnished similar reports It would be invidious to compare the work of the various hospitals, as shown by the reports of 1902 published this year, but in one of the chief hospitals I noticed a record of 40 ovariotomies with 39 recoveries, of 18 hysterectomies with 17 recoveries, of 241 herniotomies, including strangulated hernia as well as radical cure of hernia, with 233 recoveries, of 16 gall bladder operations with 15 recoveries—a record of which no hospital in the world need feel ashamed. The rise and progress of abdominal surgery have centred more around ovariotomy than any other branch of work, hence it may be of interest to review for a moment the evolution of that operation, for it has been the battlefield of abdominal work

[Mr Mayo Robson then detailed the well known controversies in which Keith in Edinburgh, Lawson Tait in Birmingham, and Spencer Wells in London took so prominent a part and showed that under perfect technique, with a judicious combination of asepsis and antisepsis, ovariotomy has become a truly beneficent procedure He continued —]

PERITONITIS.

What gives special interest to surgical affections of the abdomen is the fact that the viscera are invested in whole or in part by the large serous peritoneal sac and that infection, however communicated, is apt to assume serious proportions, involving not only the whole abdominal cavity but the system at large. In the "seventies," and even much later, the diagnosis of peritonitis used to be made with great satisfaction, as if it were final and sufficient, but I should like to ask who at the present time with any claim to scientific knowledge would be content with a mere name that gives no idea of the disease to be treated or of the cause of the illness? It may not be convenient, as has been suggested by M Aimé Guinard, that the term "peritonitis" should be altogether given up, for even at the present time it is a convenient cloak for ignorance; moreover, the public have some idea of what is meant by the term, but do not let us deceive ourselves—peritonitis so-called is an infection pure and simple of a large serous sac and the symptoms will vary with each form of organism, whether streptococcus, pneumococcus, gonococcus, or bacterium coli, as well as with the amount of toxin absorbed Accepting this view we cannot be astonished to find an acute infection associated with a lowered temperature and a rapid small pulse This paradox is so characteristic that for years one has been teaching pupils to look on a subnormal or even a normal temperature combined with a rapid pulse as serious in surgical diseases of the abdomen and as indicating the absorption of toxins If the disease were a *true inflammation we should look for the cardinal symptom*, fever, which is absent in these toxæmic cases The discovery of the frequency of perforative appendicitis, of perforating gastric ulcer, and of other peritoneal catastrophes is gradually abolishing the term "acute peritonitis" for the more rational one of "acute peritoneal infection," for the treatment of which surgery alone is of any use, and even for it to be of service, operation must not be long delayed. These more rational views of pathology and treatment have originated and developed within recent years, and I can recall case after case, during my student days, in which peritoneal catastrophes ended fatally, where now we should by timely interference give a very fair chance of life Could anything show this more definitely than the results of treatment of perforated gastric ulcers, which if operated on at once would have hardly any mortality, if within 12 hours of rupture a mortality of 16 6 per cent., if within 24 hours, 63 6 per cent., *if within 36 hours, 87 5 per cent, and if delayed* for 48 hours will only rarely succeed, or, to give another example, than the results of surgical treatment of the intestine in typhoid fever, alas, too seldom resorted to To give an example kindly obtained for me by Dr P J Cammidge out of a total number of 900 cases of typhoid fever occurring in St. Bartholomew's Hospital in the years 1895 to 1901 there were 102 deaths Among the 900 cases were 38 of perforation, of which 34 died unoperated on, whereas of the four operated on three recovered Could operation have been done in the remaining cases it would seem possible that 25 more lives might have been saved In Professor Osler's clinic, out of 11 cases five were saved by operation Intimately related to intestinal perforation is perforation of the gall bladder in typhoid fever, of which 34 cases have been collected by Dr Erdmann of New York, of these 27 were not operated on and all died, but of the seven which were operated on four recovered As spontaneous recovery from perforation is extremely rare it is of the utmost importance that not only should we have an early recognition of the perforation but also an immediate operation Up to 1883 every case of intraperitoneal rupture of the bladder had died but in that year the late Sir William Mac Cormac operated and saved two lives, *since that time there* have been 54 operations recorded, according to Dr Jones,[1] out of which 28 patients recovered Could these cases have been seen earlier, the saving of life would have been much greater, for in the cases that recovered there had only been an average interval of 25½ hours between the accident and the operation, whereas in the cases that died the average interval had been 32 hours, and of the 26 deaths 17 were due to peritoneal infection Just as in gastric ulcer, the danger is increased with every hour of delay between the accident and operation hence in case of doubt exploration (which can be done through a very small incision, just sufficient to admit the finger) is safer than waiting, and experience shows that the aiding of the diagnosis by the injection of air or fluid into the bladder adds to the risk of general peritonitis by spreading infection over the whole abdomen In injuries of the abdomen by penetrating wound, whether stab or bullet wounds, the resulting troubles are from infection, either directly through the instrument causing the injury or by perforation of one of the hollow viscera and escape into the peritoneal cavity of the septic contents How much more rational it is to consider this as an infection and immediately to set about the removal of the poison and the repair of the damage, *if it can be done under conditions* favourable to success, than to treat it as peritonitis and to rely on so-called antiphlogistic remedies. Few greater triumphs of scientific surgery can be shown than some of the remarkable cases of visceral injury where stomach, bowel, liver, gall-bladder, and other viscera have been perforated, either by bullet or some other sharp instrument, and in which operation has been successfully performed before infection has had time to occur.

---

[1] Annals of Surgery, June, 1903.

APPENDICITIS.

Appendicitis of the acute, perforating, or gangrenous type comes on so suddenly as often to constitute a peritoneal catastrophe and in a proportion of cases terminates fatally in so rapid a manner that the diagnosis is made only with great difficulty or not at all. Such cases, when I was a student, went undiagnosed and death was ascribed to peritonitis simply, a sufficient diagnosis in those days ; and it was not till 1886 that we heard anything of this lethal malady which though it has slain its tens of thousands is now, thanks mainly to the labours of Fitz of Boston, who laid the foundation of our modern knowledge of the subject, brought under subjection in a very large percentage of cases. The disease is said to be on the increase, but I am not at all clear as to the truth of this, as there have been buried in our literary records for generations, fairly accurate accounts of dangerous inflammations occurring in the right iliac fossa and described vaguely as typhlitis, perityphlitis, paratyphlitis, &c., and both Copland and Burne in 1837 gave accurate descriptions of perforative appendicitis and its consequences. It is certainly more frequently diagnosed and more scientifically treated than it was, and it is a comfort to know that the operation, when undertaken early, is attended with an encouraging amount of success, and, as shown by Sir Frederick Treves, when treated in the quiescent period it is almost devoid of risk. Arguing from my own experience of operations in the quiescent period in a large number of cases without a death, and from that of many other surgeons at home and abroad, I have no hesitation in saying that had I an attack of appendicitis I should prefer accepting the infinitesimal risk of removal of the organ directly the attack was over to the decided risk of waiting for the next seizure, which might be one of the acute type. Even in the acute type of the disease operation, if undertaken early, as is the practice advocated by some surgeons, is very successful, and though we cannot expect it to be devoid of danger like the operation between the attacks, yet it is certainly very much safer than waiting for the gangrenous process to extend, for an abscess to burrow or to burst in various directions, for infection to invade the blood, or for the onset of complications of infinite variety and danger.

[Mr. Mayo Robson then discussed at length the various methods of hysterectomy for myoma and some of the operations on and about the liver for the evacuation of hydatids and abscesses, showing how many patients by the advance of modern surgery could be relieved of what quite recently were mortal conditions. He went on :—]

THE SURGERY OF THE BILE PASSAGES.

This is one of the most interesting episodes in abdominal work, for although the first cholecystotomy was performed so far back as 1867 by Bobbs of Indianapolis it is only within recent years that surgery has come to be recognised as the treatment for gall-stones. I performed my first cholecystotomy in 1885, since which time I have operated nearly 600 times on the gall-bladder and bile-ducts. When in 1889 I read a paper before the Clinical Society of London one of the leading London surgeons said to me, "Wherever did you conjure your gall-bladder cases from: we never see them here?" I referred him to the medical wards and to the post-mortem room of any of the hospitals, with the result that within a short time he found many cases requiring relief. At first cholecystotomy only was practised, with the result that the ducts were often left obstructed and fistula necessarily followed. It was thought to be a bold venture when Lawson Tait crushed a stone in the common duct, a procedure which I followed with success on a number of occasions, until Courvoisier in 1891 showed it to be better to incise directly the common duct. Common-duct operations, as performed by the upward incision and rotation of the liver, which I introduced some time ago, are now as easy as an ordinary cholecystotomy used to be, for the improved method enables the whole of the biliary ducts to be brought near to the surface and to be deliberately dealt with. Nothing could demonstrate this better than the results in my own practice in an experience of over 100 choledochotomies, for whereas in my first series before 1900 the rate of mortality was 23·8 per cent. in my last series it is only 1·5 per cent., and I have had a continuous series of 50 cases without death ; moreover, it must be borne in mind that nearly ever one of these cases is not merely a successful operation but life saved, for common duct cholelithiasis associated wit infective or suppurative cholangitis and deep jaundice is mortal malady.

It is interesting to recall the views that were held o cholelithiasis in the "seventies," when the pathology of th disease was ill understood and the dangers were not at al realised. The first real step in the study of the pathogenesi of gall-stones was made in 1886, when Bernheim showe the relation of typhoid fever to the development of cholecystitis and the next was in 1886 when Galippe demonstrated the bacterial origin of gall-stones. Now we ma say that by whatever cause, whether through the blood o from the bowel, bacteria enter the bile channels, there i no longer a question that in bacterial infection of lo virulence we have explained the etiology of cholelithiasis Fortunately, gall-stones are usually easily diagnosed, th symptoms are classic and in the early stages before complications have supervened cholelithiasis is curable b surgical methods in 99 per cent. of cases, as I mysel have demonstrated in a large series of operations; but i we wait for complications to supervene and for the onse of jaundice and various infections, or until cancer ha invaded the liver and gall-bladder, which it does ultimatel in 50 per cent. of cases in which jaundice is present, then there will be a very different tale to tell. Even yet we do not get these cases always in time and unti the fact is grasped that medicine can, as a rule, only relieve and cannot cure cholelithiasis we shall be continually having to operate in the presence of serious complications, endangering life when operation is from five to ten times more dangerous than if it had been undertaken at an earlier stage. But you say, What about the cures at Carlsbad, Harrogate, and other spas? Well, the waters undoubtedly do relieve the catarrh so often associated with gall-stones ; and for the rich who can afford to make periodical pilgrimages thither the troubles may for a time be tided over, until, in a considerable proportion of cases, the descent of the stone into the common duct or the supervention of cancer compels more active intervention ; and fortunate it is for them if it be not too late. For the poor, to whom time wasted means starvation for those dependent on their wages, fortunately surgery holds out good hope of speedy cure.

The great reduction in mortality in surgery of the gall-bladder is due to an earlier diagnosis, a closer study of the pathogeny of the disease, and infinitely greater care in operative technique. Much work remains to be done in this region, for it is a difficult and complex field, less accessible than many other regions of the abdomen and often complicated by pancreatic troubles coexisting ; but progress is steadily being made and every year shows real advance tending towards perfection.

THE SURGERY OF THE STOMACH.

The way to success in gastric operations has been paved with many failures and only recently has the surgeon been able to show what can be done in this branch of work. For instance, when gastrotomy was first performed by Sedillot and by those who followed him it was nearly always fatal, the chief reason being that the patients were never handed over to the surgeon until nearly moribund; of such were my first eight cases, of which six died. Even up to 1890 the mortality was so great that the operation was seldom advised, yet it can be done in so short a time and with so little disturbance that out of my last 24 cases all have recovered except one, leading to considerable prolongation of life in the malignant, and to the saving of life in the simple, cases. In the "seventies" anyone with carcinoma of the stomach was at once given up as hopeless, and only in 1879 was the first attempt made by Péan to remove a malignant pylorus, the first successful operation being performed by Billroth in 1881, when the operation was looked on with as much disfavour as was the first attempted complete gastrectomy a few years ago by Connor in America, yet Schlatter's patient a little later lived 14 months after complete gastrectomy and I can point to a man in good health on whom I performed almost complete excision of the stomach two and a half years ago and to others now well who have undergone partial gastrectomy. Professor Kocher's statistics in this branch of work are of great importance as showing that the radical operation may in some cases, if done thoroughly, prove curative, and my friend Mr. Jessop has a patient now living from whom he removed the pylorus for cancer several years ago. I am firmly convinced that many deaths are ascribed to cancer when the disease is inflammatory and perfectly curable by the operation of gastro-enterostomy without removal of the tumour. This I can prove from my own experience in patients now living and well several years after an operation which at the time was thought would be only of a palliative nature. Nor was the palliative operation of gastro-enterostomy much better thought of at first, for although Wolfler successfully performed the operation in 1881, his patient surviving for four months, yet the mortality of 65·71 per cent. in the years between 1881 and 1885, of 47 per cent. in the period from 1886 to 1890, and of 33·91 per cent from 1891 to 1896, though showing a steadily decreasing death-rate, yet presented so doleful a picture as to deter medical men from recommending their patients to submit to operation. Even so recently as 1900, when I gave the Hunterian Lectures on the Surgery of the Stomach, of the 1878 cases of gastro-enterostomy that I was able to collect from all sources the mortality was 36 4 per cent. But since that time the surgery of the stomach has made such rapid progress that of 103 posterior gastro-enterostomies which I myself performed up to December, 1902, *for various diseases, including* cancer, there was a mortality of only 3·8 per cent.

Until quite recently gastric ulcer, except for one or two of its complications, has been considered to be a subject for medical treatment from first to last. The profession is, however, becoming awakened to the fact that it is not the trifling ailment it was once considered to be and that it should from the first be taken seriously, for it is in the early stages that medical treatment can be employed to the best advantage and in the later stages that general treatment is so often followed by relapse or by serious complications. Leube, one of the greatest medical authorities on the subject, says that one-half or three-fourths of all cases will be cured by four or five weeks of treatment, but if not better in that time they will never be cured by medical treatment alone; and Einhorn says it is fatal directly and indirectly in 50 per cent. of cases when reliance is placed exclusively on medical treatment. It can be demonstrated that in the patients incurable by medical means surgery holds out a good hope of relief or cure in 95 per cent. of cases, as I have shown in an address recently given before the London Polyclinic. The subject is too large to enter minutely into, but from what I have stated now and in other places have given in detail it will be seen that in this, as in other diseases of the stomach, modern surgery has very great triumphs to record.

THE SURGERY OF THE PANCREAS

The pancreas had practically received no attention from a surgical point of view up to Senn's classical experimental work in 1886 and even for some time after that the only interest centred around cysts, so that Greig Smith, writing in 1896, said, "The experience of the last ten years has added little to the work of Senn of Chicago." But what do we see to-day? That the subject is of such magnitude as to need a volume of considerable size to deal adequately with its pathology and surgical treatment. I myself have operated on nearly 100 cases of disease of the pancreas of various kinds. Acute pancreatitis is one of the most serious and fatal of diseases, often coming on with startling suddenness, and it is astonishing how it can have escaped the notice of pathologists until so recently. Fortunately, surgery has been able to interfere beneficially in some of these cases, especially those ending in suppuration, and as our knowledge of the subject increases we shall be able to do more both in the way of prevention and cure. Chronic pancreatitis, though recognised from a pathological point of view, was practically unrecognised as a subject for surgical treatment until I drew attention in June, 1900, to the facts derived from an experience extending over some years that many cases described as cancer of the head of the pancreas and leading to chronic jaundice, which ended fatally, were really cases of chronic pancreatitis that could be cured by draining the pancreatic duct indirectly through the bile passages; this has led to great success in the treatment of a class of cases previously treated as hopeless. As yet the treatment of cancer of the pancreas is very unsatisfactory, and whether we shall ever be able to do much for malignant disease in this situation the future alone will prove; for although a portion of the pancreas has been removed with success in one or two cases it is an operation not likely to be frequently repeated and the cure must be sought in that extended knowledge of cancer generally which we are all striving for. The treatment of cysts is most successful and it is now well established that by drainage we may reasonably expect to cure or materially to relieve the patient in a very large proportion (probably from 93 to 95 per cent.) of cases. Calculus of the pancreas is a disease about which very little has been heard and still less done but of which more will be recorded in the future. A case of removal of calculus was described by my friend Mr. A. Pearce Gould in 1895 in which the patient survived the operation for 12 days; there was one last year in which my friend Mr. B. G. A. Moynihan successfully removed a calculus through the duodenum; and in February of this year I operated and removed three calculi from the pancreas, one from the gland by the side of the common duct, one from the main duct which it was obstructing (that being reached through the duodenum), and one of about the size of a cobnut from the main pancreatic duct on the left of the spine, this being the first case in which the main pancreatic duct has been deliberately opened through the substance of the pancreas and stitched up again after removing the obstruction. The patient recovered. The more complete exposure of the pancreas which can now be obtained by the method I have suggested for exposure of the common bile-duct will give an impetus to pancreatic surgery and will render the operative technique both easier, safer, and more certain.

THE SURGERY OF THE INTESTINES.

The interrupted suture at first employed occupied so much time in application that many modifications were soon introduced and in 1885 Mr. Stanmore Bishop showed that there were no fewer than 33 distinct methods of enterorrhaphy and since probably as many more have been introduced. In 1887 Senn's plates were employed to facilitate the process of intestinal anastomosis and I remember what a great impetus was given to the surgery of the intestinal canal by Dr. Senn's very able paper and demonstration at the International Medical Congress in Copenhagen. In 1892, being dissatisfied with the methods then in vogue, I invented a decalcified bone bobbin shaped like a cotton reel which would form a temporary splint around which to apply two continuous sutures—one to the serous and another to the mucous margin of the new openings—which method has proved most useful and I feel sure has administered to whatever success I have had in this line of work. The continuous sutures applied over the bone bobbin considerably shortened the time of operation and left the union so safe and secure that in a large number of operations since performed on the hollow viscera I have continued to employ it with great satisfaction. As illustrating its utility the series of cases of posterior gastro-enterostomy performed by me up to the end of last year were all done by this method and in the four cases that died the union, as proved by necropsy, was perfect, moreover, I know that the anastomotic opening has not the tendency to contract that occurs after some of the other methods and as the bobbin dissolves within two or three days no foreign body remains to cause further trouble. In end-to-end junction of the divided bowel in enterectomy the decalcified bobbin has given me equal satisfaction and though from the nature of the cases the actual operative mortality has been greater yet in no case has the result been due to imperfect coaptation. In 1892 Dr. Murphy of Chicago invented his well-known metal button which, since it is employed without previous application of sutures, can be used very quickly and by its distinguished inventor as well as in the hands of other surgeons it has been adopted with great success. The chief disadvantages it presents are, first, that it is necessarily associated with sloughing of the compressed and coapted ends of the bowel; next, that a foreign body is left in the canal which sometimes produces ulceration and other troubles; and thirdly, that the opening has been found in some cases to contract and this necessitates a further operation. Along with many other surgeons I gave it a thorough trial, but soon reverted to the method of suture round a bobbin, and the general trend of opinion is now to rely on simple suturing with or without any mechanical support. Cases of tumour of the bowel when I was a student were given up as hopeless, though a little later colotomy was performed as a means of giving relief, which was of course merely temporary. At the present time such growths are removed before the supervention of obstruction and with very good results both immediate and remote; for instance, my colleague, Mr. H. Littlewood, recently reported a series of 14 colectomies with 10 recoveries, and out of 38 enterectomies which I have performed 26 have recovered, but out of my last 16 in private 15 recovered, showing the progress that has been made in the operative technique.

It is astonishing what large portions of the intestinal tract may be taken away with safety; for instance, Mr. Barker removed five and a half feet of damaged bowel with success in a case of strangulated gangrenous hernia, and I have on several occasions removed part of the ileum, the cæcum, the ascending and part of the transverse colon, with recovery of the patient. In the first number of the *International Archives of Surgery* is the description of a case in which Professor Roswell Park removed eight feet nine inches of gangrenous small intestine, the patient being well a year later; and in the same paper reference is made to 17 other cases in which over six feet of bowel had been excised with recovery in 14; in one of these cases no less than 11 feet were removed. In 1884 colotomy had the enormous mortality of 31·6 per cent. for the lumbar and 53·1 per cent. for the inguinal operation, as shown by Dr. W. R. Batt, who collected the records of 351 cases; in 1889, under improved technique, the inguinal operation was reintroduced by Mr. H. W. Allingham, with the result that the mortality was diminished within a short time to under 10 per cent., even including cases of acute obstruction, though excluding the acute cases the mortality is under 5 per cent. Looking to the future it seems highly probable that colotomy will be largely replaced by the removal of the disease, for it has been clearly proved that there is no part of the lower bowel which cannot be safely excised if taken sufficiently early, and I can point to a number of patients living in comfort from whom I removed rectal cancer years ago, in one the patient being in good health ten years after. Mr. W. Watson Cheyne estimates the mortality of excision of the rectum at from 5 to 10 per cent. and refers to Kocher's statistics in which 28 per cent. of cases remained well from three to 16 years after proctectomy.

For the rational treatment of intestinal obstruction we owe much, first, to the anatomical researches of Sir Frederick Treves, and secondly to his admirable work on the pathology and surgery of the subject. Although there are vague accounts of a successful operation for volvulus in 1768, the surgery of the last century until within 20 years of its close had no history bearing on the subject of intestinal obstruction, and I can remember when it was considered no discredit to stand by with folded hands while a patient was dying from internal strangulation. Many of those present will remember it being proposed seriously less than 20 years ago, in one of the medical societies, by a very eminent surgeon, that operation could be frequently avoided by calling in the nearest policeman and suspending the patient head downwards with the knees bent over the constable's shoulders, who was then directed to jump up and down a number of times so as to displace the hernia or to undo a twist; this will show the state of intestinal surgery in the "eighties." At the present day the differential diagnosis has been so well worked out and the technique of operative work so much improved that no physician or surgeon long delays resorting to operation if relief be not soon obtained and the results as shown by numerous reports amply justify the change. Did time permit I could give numerous examples of the cure of acute intestinal obstruction by the division of bands, the untwisting of volvulus, the unfolding of intussusception, the reduction of internal hernia, and the removal of concretions, in all of which, but for the recent advances of surgery, the patients must inevitably have perished and all of whom would undoubtedly have died had they occurred in the "seventies."

[Mr. Mayo Robson then discussed the value of operative procedure in abdominal tuberculosis and strangulated hernia, going on to discuss the advances made in surgery with regard to the treatment of—]

THE ANOMALIES OF PREGNANCY.

Eminently satisfactory results are now obtained in that ancient operation, Cæsarean section, where at one *séance* two, or sometimes three, lives are saved and which in the hands of Murdoch Cameron, Leopold, Sanger, and other operators has been done in recent years with an extremely small mortality, whereas in the large maternity hospitals in Paris during half a century before the aseptic era, although the operation had been done 60 times, in no instance had the mother's life been saved, and in England the operation for similar reasons was condemned absolutely. I know of no operation that has given greater satisfaction than this one, for the patients are eternally grateful, which is truly the highest reward of the surgeon. Dr. J. M. Amand Routh has been kind enough to furnish me with statistics showing the improvement in the operation of hysterectomy performed at or near the full term of pregnancy for contracted pelvis, cancer of the cervix, or obstructing fibroids. From 1876 to 1881, out of 99 cases there was a mortality of 60·6 per cent.; from 1887 to 1901 out of 311 cases the mortality was reduced to 16·7 per cent.; and while the extraperitoneal treatment of the stump had a mortality of 31·3 and panhysterectomy one of 21, the retroperitoneal method of treating the stump only gave a rate of 16·6 per cent. Ovariotomy during pregnancy has been remarkably successful, the mortality for a large series of collected cases being only 5·19 per cent., and the recovery after operation being as satisfactory as in ordinary circumstances. Ectopic gestation until recently constituted a dark chapter in medicine; it was altogether misunderstood as to cause, pathology, symptoms, and treatment, and hundreds of lives were lost annually which are now saved by timely surgical intervention. To the genius of Lawson Tait, who utilised the post-mortem experience of Bernutz and Goupil published in 1886, and the clinical observations of J. S. Parry we owe the successful treatment of this otherwise fatal disease. Lawson Tait's work on this subject alone should be sufficient to establish a claim for him to be placed among the great benefactors of science and of humanity. As showing the success of his treatment from the first, up to 1887 he had operated 35 times for ruptured tubal pregnancy with only two deaths and in my valedictory address at the termination of office as President of the British Gynæcological Society in 1898 I was able to report, following on the same lines, 23 operations for ectopic gestation with one death. The subject has received much attention at the hands of Professor J. W. Taylor of Birmingham, Mr. J. Bland-Sutton, and others, but only recently has it been distinctly proved by four undoubted cases, one of which came under my care, that ovarian gestation is a possibility. The subject is replete with interest and it may be said without any fear of contradiction that this operation alone has saved many thousands of lives which, when I was a student, would have been sacrificed and probably certified as having died from internal hæmorrhage.

THE SURGERY OF THE KIDNEYS AND URETERS.

Although the dawn of renal surgery dates from August 2nd, 1869, when Simon of Heidelberg deliberately performed nephrectomy, the first successful operation in England was done by a member of your Council, my respected colleague, Mr. T. R. Jessop, an operation which I had the privilege of witnessing. Sir Thomas Smith advocated nephrotomy in 1869 before Simon's operation, but it was not until 1870 that Mr. Bryant first performed the operation and until 1880 that Mr. Henry Morris applied it to the removal of a calculus. As showing the advances that followed, the last-named surgeon was, in 1898 able to report 34 nephrolithotomies with 33 recoveries, showing the invalidity of the objection which had before 1880 been urged against the proposal to operate on a kidney not already converted into a mere abscess sac, and proving that the conservation of the kidney by removal of the disease is infinitely better than the sacrifice of the organ which was at one time advocated. The next advance was due to Hahn who in 1881 described two cases in which he had performed the operation of nephropexy for the fixation of moveable kidney, a procedure which in proper cases confers great benefit on a class of patients who previously had to bear their troubles until the moveable organs were often converted into large fluid cysts owing to intermittent kinking of the ureters. By utilising the partly-stripped capsule and the posterior incision of Edebohl I have been gratified with the results, both immediate and remote, of the operation, which with little or no risk in properly selected cases has been the means of restoring many invalids to a state of health and comfort. Partial excision of the kidney as a conservative operation is the next advance to chronicle. Czerny in 1887 excised part of the organ for tumour, preserving the remainder of the kidney which seemed to be free from disease; this was followed by a number of conservative operations by Tuffier, Kimnell, Bloch, Morris, myself, and others, many of which have been completely successful; for instance, I know of a lady in perfect health from whom I removed a large wedge from the centre of the right kidney for localised tuberculous disease some years ago, of another from whom I removed the upper half of the right kidney for growth which apparently started in the suprarenal capsule and who was well three years later; and of other cases in which formerly one would have considered it absolutely essential to remove the whole organ. The differentiation of diseases of the kidney—a great advance in diagnosis—has been rendered much more certain by catheterisation of the ureters, which I was privileged to be amongst the earliest to do in 1886, but to Kelly of Baltimore is due the credit of working out the subject systematically and demonstrating with what facility it may be done Already, however, this is replaced by a much superior method, the idea of E Lambotte of Brussels who in 1890 invented an instrument which when passed into the bladder collects the urine from each side and conveys it to two separate bottles The invention in 1898 of a segregator by Harris of Chicago has still further extended the usefulness of this method, so that there is now no longer need for doubt in any case as to whether the disease is limited to one or involves both kidneys The most recent advance in renal surgery has been in the treatment of chronic nephritis or Bright's disease, which was first drawn attention to by my friend Mr Reginald Harrison who recommended renal puncture or incision in certain cases of chronic albuminuria, but to Edebohl of New York must be given the credit of adopting an original operation for the treatment of Bright's disease He in 1898 deliberately exposed both kidneys, stripped their capsule, and fixed them in position in a young woman, aged 26 years Frequent examinations during the five years showed in every instance normal conditions and the patient has recently married and is well In March of this year Edebohl reported 51 cases of renal decapsulation and in 47 of these cases both kidneys were operated on at the same time Out of this large number 22 are said to be improving from three to 15 months after operation As yet it is too early to pronounce a definite opinion on the procedure but it is an undoubted fact that decapsulation does effect some improvement in this serious malady, and it may possibly prove effectual in saving life in those terrible cases where suppression of urine comes on after some trifling operation, such as catheterism, or after a chill, or in scarlet fever, just as surgery has effectually stepped in and saved life where suppression was due to obstruction of both ureters We may certainly go so far as to say that no patient ought to be allowed to die from suppression of urine without the surgical question being considered

[Mr Mayo Robson then referred to the possibility of success attending the organised search into the cause of cancer, to recent successful developments in serum therapy, and to Professor Wright's researches, as published in THE LANCET,[3] with regard to localised staphylococcus infection and concluded his eloquent address thus —]

Gentlemen, I have tried to show that the advances in treatment during the past third of a century have been commensurate with our increased knowledge of disease and simply on account of time have I limited myself in a great measure to diseases of the abdominal cavity I have tried to show what a close connexion exists between the science and art of our profession and how very necessary it is, if we are to continue our march of progress, that experimental research should not only be untrammelled by factious and unreasoning opposition, but that it should receive greater recognition, encouragement, and support at the hand of the public I have tried to forecast the future and to show that while surgery has still great strides to make and many difficulties to conquer, such progress will be in a great measure intimately bound up with the work of the physician, the pathologist, and the bacteriologist, and I think the time will come when preventive measures such as I have portrayed will save much operative work and when it will be thought a greater triumph to prevent than to cure disease We can see that methods and policies which were sufficient years ago are totally inadequate to day We may modify but we cannot prevent the world's advance, and while times change men change with them The medical profession is imbued with a spirit that half a century ago was undreamed of Not only have apparently insurmountable difficulties been overcome, but habits of thought have been attained which have made such achievement possible, and a scientific attitude of mind has become characteristic of our profession, as it has of the leaders in every branch of the world's progress In becoming more scientific it is a mistake to suppose that the medical profession has lost touch with higher beliefs As Lord Kelvin has so happily stated it lately, "Science positively affirms creative power We only know God in His works, but we are absolutely forced by science to believe with perfect confidence in a directive power, in an influence other than physical, or dynamical, or electrical force" There is no harm in free thinking, for if we think strongly enough we are forced by science to a belief in a higher power, which is the foundation of all religion. In conclusion, I must thank you for giving me so patient a hearing and at the same time I would apologise for many conscious omissions which had time permitted would not have occurred I trust, however, that what I have said will serve to show that we are one and all imbued with a desire to carry out our duties conscientiously and to live up to the privileges of our high calling

The Milroy Lectures

ON

THE CAUSES, PREVALENCE, AND CONTROL OF PULMONARY TUBERCULOSIS.

Delivered before the Royal College of Physicians of London on March 5th, 10th, and 12th, 1903,

BY H TIMBRELL BULSTRODE, M A,
M D CANTAB, D P H,

INSPECTOR MEDICAL DEPARTMENT, H M LOCAL GOVERNMENT BOARD; LECTURER ON PREVENTIVE MEDICINE CHARING CROSS HOSPITAL MEDICAL SCHOOL

LECTURE II (*concluded*)[1]

Delivered on March 10th

THE BEHAVIOUR OF TUBERCULOSIS IN ITALY

IT would appear from the statistics[2] which are available for the kingdom of Italy that if we consider in one group all forms of tuberculosis there has been since the year 1888 a decided tendency towards decrease In 1887 the mortality

TABLE X —SHOWING THE MORTALITY IN ITALY FROM [illegible] PER 1,000,000 OF THE POPULATION FOR EACH OF [illegible]

—	1887	1888	1889	1890	1891	1892	1893	1894	1895	1896	1897	1898	1899

[3] THE LANCET, March 29th, 1902 p 874

Some epidemiologists in this country will regard the prophecy of Major Gorgas as somewhat too optimistic. They will wish to know something as to the introduction of better diagnostic methods and as to better registration made use of by the Americans before they can accept the figures as a basis for the inferences arrived at. For my own part I will withhold criticism, for as regards yellow fever it must, I think, be admitted by all fair-minded persons that the work of the Americans in Havana has resulted in perhaps what must be regarded as the most remarkable victory ever achieved by preventive medicine. These Havana statistics with regard to tuberculosis furnish the most hopeful picture which I shall be able to show you. If they are sound they serve to show what an enormous amount may be effected by well-organised education and without the aid of either sanatoriums or hospitals for advanced cases.

And here, Mr. President, I would ask for your indulgence while I have thrown upon the screen a table which has been taken from an address recently delivered by Sir Patrick Manson before the Epidemiological Society of London and which illustrates the behaviour of yellow fever in Havana during the period of the American occupation (see Table XVI.). I make this request, not only because the figures have obviously some bearing upon those we have just considered, but also because I should be glad to be allowed to show here my deep appreciation of the epoch-making and truly heroic work of our American *confrères* in connexion with the etiology, the pathology, and the control of yellow fever.

This table apparently teaches us many lessons. It shows us what may be done by a vigorous and dominant race, sparing no time, energy, or expense to apply the lessons learnt, not in the laboratory, but in wards in which men freely allowed themselves to be experimented upon in order to prove or to disprove a laboratory thesis. The table illustrates, too, what victories may be secured for preventive medicine when she is engaged in warfare with a foe which is itself the host of the specific parasite against which her efforts are directed. In the case of yellow fever the war is against the *stegomyia fasciata* and its larvæ. Both may be destroyed. But in tuberculosis the host, or rather the only host with which we are here concerned, is the human species, and we can destroy neither the mother nor her progeny, nor can we, for it may be for years, separate the one from the other.

* Year of American occupation.

N.B.—This table is taken from a paper recently read before the Epidemiological Society of London by Sir Patrick Manson.

Were we dealing with bovine tuberculosis alone we might, by adopting in their entirety the methods of Professor Bang, practically eliminate bovine tuberculosis, but the only method which occurs to me of at once stamping out tuberculosis in the human species is to segregate all those who react to the tuberculin test and the application of the same test to each traveller reaching our shores. We can act in this fashion, but only to an uncertain degree, in the acute specific diseases, lasting at most two months, but there are obviously difficulties in applying the same method to a disease from which apparently some 25 per cent. of the people suffer at one or another period of their lives and for prolonged periods.

THE BEHAVIOUR OF PULMONARY TUBERCULOSIS IN NORWAY.

I am anxious to place before you the statistics of Norway, because in my last lecture I shall draw attention to some very embracive measures which have recently been brought into operation for the control of this disease. For these statistics (see Table XVII.) I am indebted to Dr. Holmboe, the Director of the Civil Medical Service. It will be seen from these figures that the disease in question is evincing an upward rather than a downward tendency.

TABLE XVII.—*Showing the Death-rate from Pulmonary Tuberculosis per 10,000 of the Population in Norway.*

Year.	The kingdom.	The towns.	The rural districts.
1893	18·0	27·0	15·0
1894	18·0	28·0	15·0
1895	18·7	29·0	15·0
1896	19·0	26·0	16·0
1897	20·0	27·0	17·0
1898	21·0	29·0	17·0
1899	22·0	29·0	19·0
1900	22·0	27·0	20·0

The average rates for the three years 1898–1900 ranged in different parts of the kingdom from 11·0 to 45·0 per 10,000.

THE BEHAVIOUR OF PULMONARY TUBERCULOSIS IN ENGLAND AND WALES.

Most of my hearers are, I expect, fully acquainted with the behaviour of pulmonary tuberculosis in this country and I will therefore devote but a short space to its consideration. I have, however, been curious during my researches to ascertain how far Professor Koch's thesis, that the decline and the death-rate in most civilised countries are to be ascribed mainly to the better knowledge of the disease which has resulted from the discovery of the bacillus, receives illustration in this country.

In order to apply this view to England and Wales I have taken the rates for pulmonary consumption for each of the three five-yearly periods preceding the period 1881–85, during which time the tubercle bacillus was discovered, and I have compared these rates with those of the three five-yearly periods which succeeded 1881–85. After due consideration, this appears to me to be the fairest method, but I shall be very glad to reconsider the question in the light of any other [illegible] d enough to suggest. [illegible] the accompanying table [illegible] that during what we may [illegible] e death-rate per 10,000 from phthisis fell from 24·4 to 20·3, that is 4·1 per 10,000, whereas during the 15 years succeeding the period during which the bacillus was discovered the rate fell from 16·3 to 13·2, that is to say 3·1 or 1 per 10,000 less than it fell in the pre-bacillary stage.

TABLE XVIII.—*Showing the Deaths from Pulmonary Tuberculosis in England and Wales per 10,000 of the Population for each Quinquennial Period from 1866 to 1900.*

1866–70	24 4	1881–85 ...	18 5	1886–90	16·3
1871–75	22·1			1891–95	14 6
1876–80	20·3			1896–1900	13 2
(Difference 4·1—i.e., a percentage fall of 16 8.)				(Difference 3·1—i.e., a percentage fall of 19 0.)	

We have then a slightly increased rate of fall after 1881–85 as compared with the rate prior to that period. Obviously the rate decreases as the base line is reached, but so far as [illegible] ere was some factor—[illegible] bacillus involved—which [illegible] d with a force almost as great as was the case during the 15 succeeding years in which a more intimate knowledge of the morphology and biology of the tubercle bacillus has been disseminating.

THE BEHAVIOUR OF PULMONARY TUBERCULOSIS IN AUSTRALASIA.

I am indebted to Major J. S. C. Elkington for drawing my attention to an interesting account by Mr. T. A. Coghlan, statistician of New South Wales, on the behaviour of pulmonary tuberculosis in Australia.[5] Mr. Coghlan points out that although pulmonary tuberculosis claims more victims than any other disease, the death-rates from this disease are lower in Australasia than in other parts of the world. This is the case notwithstanding the fact that as the Australian climate is regarded as favourable to those who suffer from consumption many patients afflicted with this disease are imported into the colonies for curative purposes; indeed, it is estimated that some 7 per cent. of those who die from pulmonary tuberculosis in the Australian colonies have been resident therein [illegible] ing tables (Tables XIX [illegible] Coghlan's work, wo [illegible] pulmonary tuberculosi [illegible] of Australasia, but that since that date a steady decline has taken place.

TABLE XIX.—*Showing the Deaths from Pulmonary Tuberculosis per 10,000 living in Australasia.*

Tasmania...	6 48	5·96	6 72	6 46	6 50	6 01
New Zealand	*6 46	7·14	8 32	8 50	8 03	8 47
Australasia	6 61	7·35	8 26	8 19	8 04	7 49

* Four years, 1872–75.

As regards the separate colonies Victoria yields the highest death-rate, Queensland coming next, and Western Australia last. With respect to the high Queensland rate both Mr. Coghlan and Dr. A. Jefferis Turner[6] attribute it to the excessive mortality from pulmonary tuberculosis of the South Sea Islanders and in this connexion Dr. Turner furnishes some tables which tend to the conclusion that in Queensland this disease among the white population is on the decrease.

It will be seen from the accompanying table (Table XXI.), compiled by Dr. Turner, that during the period 1891 to 1900 the tendency of pulmonary and other forms of tuberculosis has been slightly downwards, whereas the tendency of pneumonia, cancer, and heart disease has been upwards.

TABLE XXI.—*Showing the Mortality in Queensland from Consumption, other Tuberculous Diseases, and all Tuberculous Diseases, as compared with the Mortality from Pneumonia, Cancer, Heart Disease, and Typhoid Fever per 100,000 Mean Population in each year.*

Year.	Deaths per 100,000 from						
	Consumption.	Other tuberculous diseases.	All tuberculous diseases	Pneumonia	Cancer.	Heart Disease.	Typhoid Fever.

1898	85	17	102	73	46	40	30
1899	80	16	96	53	48	47	29
1900	87	15	102	63	47	40	23

But the fall in the death-rate from tuberculosis, so far as the white population is concerned, is only apparent and it will be seen from the next table (Table XXII.) that when the deaths are separated out the decrease is due to the diminishing number of Pacific Islanders whose deaths are attributed to pulmonary tuberculosis.

TABLE XXII.—*Showing the Number of Deaths in Queensland from Consumption classified according to Birthplace.*

Year.	Birthplace		
	Pacific Islands.	Australasian States and Colonies.	Elsewhere.
1891	187	57	257
1892	123	62	243
1893	124	89	263
1894	117	63	266
1895	95	67	233
1896	108	58	252
1897	91	52	245
1898	65	83	267
1899	66	110	231
1900	79	114	234

A further study of the figures, however, reveals the extremely interesting fact that the augmented mortality among the whites is wholly to be attributed to the deaths of those born within the Australian dominions, there having

[6] Report on the Proceedings of the International Congress for the Preventi [illegible] year 1901, by A. Jefferis [illegible] Representative of the St [illegible]

It will be seen that the increase was greatest between 1881 and 1891 and that the difference between 1891 and 1901 was but slight. Table XXVII. is also instructive as showing that in 1871 the death-rate from pulmonary tuberculosis in Ireland was 4·2 per 10,000 below that of England and Wales. In 1901 the English rate was 8·8 per 10,000 below the Irish rate. These figures suggest many interesting fields for further inquiry, but I cannot now devote more than a very small space to the subject. It may, however, be noted that the rates for Ireland compare favourably with those of certain other countries which have come beneath our notice in this lecture, save that in Ireland there has been no such decrease as has been elsewhere observed. It will be of interest if I furnish herewith the rates for the several forms of tuberculosis for the last 11 years (Table XXVIII.).

TABLE XXVIII.—*Showing the Death-rates in Ireland per 10,000 Persons Living for the last 11 Years.*

Year.	Tabes mesenterica.	Tuberculous meningitis.	Pulmonary tuberculosis.	Other forms of tuberculosis.
1891	2·0	1·7	21·4	2·1
1892	2·4	1·9	21·6	1·9
1893	2·1	1·8	21·4	2·1
1894	2·0	1·3	20·9	2·0
1895	2·0	2·5	21·4	2·1
1896	1·7	2·4	19·9	2·2
1897	2·2	2·5	21·5	2·3
1898	2·3	2·6	21·4	2·5
1899	2·3	2·7	21·0	2·3
1900	2·2	1·6	22·5	2·2
Average 1891–1900	2·1	2·1	21·3	2·2
1901	2·3	1·4	21·4	2·4

It is possible that the small increase noted between 1891 and 1900 may be apparent only and that such rise may be accounted for by the recognition, and therefore classification, of cases which formerly found a place under some other heading. But it is of course difficult to determine what in any given case is the result statistically of a better recognition of a disease.

I have had the pleasure of discussing this question of the increase of tuberculosis in Ireland with Mr. Stafford and he has been good enough to send me some of his preliminary reflections upon this interesting subject. He writes: "I am very interested to ascertain approximately to what extent tuberculous disease depends upon (*a*) infection; (*b*) density of population; (*c*) general insanitary conditions; (*d*) climatic influences; (*e*) economic causes. Without in any way desiring to cast a doubt upon the important influence of infection as a means of distributing the disease, I fear we may possibly lose sight of the more responsible factor which is at the bottom of the whole question—I refer to economic causes. I am inclined to look upon all the others I have mentioned merely as the agents acting upon a population which from economic causes is unable to resist the disease. Whilst I do not for one moment suggest that we should not vigorously attack these agents and do great good by so doing, if we desire to get down to the bed-rock we must deal with the question upon an economic basis. I am at present engaged in some researches somewhat on the lines of Mr. Rowntree's York experiment with a view to ascertaining how the working classes of Dublin live. I do not wish to anticipate the result of these investigations, but I believe they will show a general condition of deplorable poverty and an unduly large proportion of underfed, badly clothed, and generally ill-nourished men, women, and children, endeavouring to live under conditions which, to say the least of it, are not conducive to longevity. The result in Dublin is a very high general death rate and an exceptionally high rate of mortality from tuberculosis. Throughout this country the steady outflow of the healthiest amongst the male and female population does not tend to improve the physical condition of the race, as in addition to draining away the fittest and depriving the country of their labour we have left at home to keep up the stock what are comparatively speaking the weaklings. We have, therefore, in addition to ordinary public health administrative measures, if we wish to deal effectually with tuberculosis, to face grave economic problems. In England you have reduced your death-rates generally, and your tubercular death-rate in particular, because you have improved the condition of the people. Higher rates of wages and a better standard of living, together with better housing and improved sanitation, are the means by which the improvement has been carried out." I may add that those who are interested in this question will find a thoughtful paper in a recent number of the journal *Tuberculosis* by Mr. Robert Brown, honorary secretary of the Ulster Branch of the National Association for the Prevention of Consumption.

Some will doubtless contend that the reason why tuberculosis does not decline in Ireland is the absence of notification and other direct measures, but that this is only one of the minor factors in the problem must, I think, be apparent from the fact that the disease had been rapidly diminishing in England and in certain other countries in the entire absence of any such measures as notification, isolation, disinfection, or the limitation of promiscuous expectoration. All these measures should so far as practicable certainly be taken and the Local Government Board for Ireland has recently issued some excellent leaflets directed towards this end. I am glad, too, to see that Sir Douglas Powell has visited Cork with a view to encourage the foundation of a local branch of the National Association for the Prevention of Consumption. In the able address which Sir Douglas Powell delivered he stated, *inter alia*, that "the prevention of consumption involves a much wider issue than the circumvention of the bacillus. ...... The abolition of the Corn Duties and other Free Trade legislation and improved rates of wages have done more to diminish the death-rate from consumption than any notification law against the disease would have been likely to have effected." With this view I am much in sympathy and it seems to me that the apparent behaviour of tuberculosis in different countries, and more particularly among certain races and blends of races, suggests that the condition of the host should receive more attention than it has hitherto done. I am gratified in this connexion to find myself in agreement with such an eminent authority as Sir Dyce Duckworth when he says that "some of our younger physicians are inclined to reckon without their host."[8]

The modern treatment of tuberculosis must be regarded as being directed almost solely towards the alteration of the tissues of the host in such fashion as to render them immune to the operations of the parasite which has already obtained a hold upon the tissues. Although we find in sanatoriums the greatest care being exercised with regard to the parasite outside the body the main efforts of these institutions are directed to the destruction of the parasite inside the body. It is certainly desirable to destroy the parasite wherever it is found or likely to survive, but no one can well attach so much importance to disinfection, &c., as is to be attached to the steps taken to promote the resistance of the tissues against the bacillus.

In connexion with this subject of the control of tuberculosis there is, I venture to think, too great a tendency to assume that the discovery of the tubercle bacillus has fundamentally changed the face of affairs. But this is in no sense the case. The natural history of the disease has not become modified merely because we have unearthed one of the essential agents by which nature works her ends. The fact that the bacillus is contained in the dried sputum and in the droplets given off by the subjects of pulmonary and laryngeal tuberculosis during coughing and speaking does not enhance the degree of communicability of the disease, albeit the knowledge that light and air are prejudicial to the vitality of this bacillus should enable us the better to employ both these agents in the battle against the disease. But it is of equal importance for us to determine, if possible, precisely what are the conditions under which for many years past both in this and other countries, and in the absence of measures aimed directly at the disease, its manifestations in the human species have been diminishing in extent. It would appear not unlikely that in this falling phthisis-rate we may be reaping the result of the several measures which have been aimed directly against other diseases and against general insanitary and unwholesome conditions Such measures have comprised the provision of more air, more light, greater cleanliness, better houses, cheaper food, and a better appreciation of the laws making for our general well being

---

[8] The Clinical Importance of the Personal Factor in Disease, by Sir Dyce Duckworth, M.D., LL.D. Edin. (Sonderabdruck aus der Berliner Klinischen Wochenschrift, 1902, No. 16.)

Do not, therefore, let us accept without further examination, and in face of some of the facts herein set forth, the view that the reduction of the disease has been the result in the main of the discovery of the tubercle bacillus, because this is it seems to me, a view which is not unlikely to concentrate our efforts too much upon one side of the problem Above all, let us be cautious lest in concentrating our attention too exclusively on the bacillus we may divert the tide of energy and financial support from the continuance of those indirect measures which have apparently done so much not only for the reduction of pulmonary tuberculosis but also for the abatement of multiple other conditions detrimental to health and well being

A CASE OF RECURRENT VARIOLOID RASH FOLLOWING VACCINATION

BY R W O PIERCE, B Sc , M B LOND , D P H CAMB ,
MEDICAL OFFICER TO THE GUILDFORD GODALMING, AND WOKING JOINT HOSPITAL BOARD

A BOY, aged 15 years, whose primary vaccination took place at seven years of age and was said to have been normal, was, in common with a large number of other boys attending the same school, revaccinated on Dec 5th, 1901, with calf lymph of a well known make The lymph was obtained in batches of 24 or 48 tubes and each tube served for the vaccination of two boys Nothing abnormal occurred except in the case of the boy in question who, like the others, was one of two vaccinated from the same tube His vaccination was successful and nothing unusual was noticed about the arm The boy left for his home in the north on Dec 16th and was seen on the same day by his medical attendant to whom I am indebted for the following history "He came home on Dec 16th suffering from mumps [which had been prevalent at the school] and was at once sent to bed and isolated On Dec 24th—i e., 19 days after vaccination—small pox showed itself, being ushered in by febrile excitement, with increase of temperature, &c The vesicles were numerous on the face, a fair sprinkling on the body, arms, and legs, and many on the hands and feet, including the palms and soles The vesicles had the usual amount of areola. I do not remember if there were any in the mouth, though there were many on the lips The eruption developed fully and followed the normal course The general symptoms were mild He was carefully isolated at home for six weeks The scabs from vaccination were still on the arm when he returned home and he was steadily recovering from mumps when the small pox showed itself "

On Feb 22nd, 1902, the boy returned to school apparently quite well On March 4th he was seen by the medical officer on account of conjunctival catarrh and on the 5th was placed in the school sanatorium which happened at that time to be empty On the 6th he developed three or four vesicles of large size about the upper lip and alæ of the nose which, in connexion with his conjunctival catarrh, were taken to be herpetic The main part of the eruption appeared on the morning of the 7th On that evening I saw the boy for the first time and the following are the rough notes which I took then and on subsequent days —

scrotum and a few scattered over trunk and l s
One large soft bleb on upper lip and a hard vesicle or two near nostril and on forehead Rash very irritating

In view of the typical character and distribution of the rash (except, perhaps, that on the face) a diagnosis of modified small pox was made In this the medical officer to the school concurred and the diagnosis was confirmed during the next two days by two experienced medical men who were called in The only other occupants of the sanatorium—viz , the nurse and the maid—were successfully revaccinated at once I next saw the case on the 9th (two days later) when the condition found was as follows —

Rash
feel has
become
backs of
some co
of an in
flatter s
rough sl March 10th —Rash on back of hand about the same as yesterday but in a few pocks there is a small central vesicle or pustule over central dot or umbilicus and the surrounding part of vesicle seems more fleshy and devoid of contents as if contents of vesicle had exuded laterally and uniformly into the surrounding skin No raised vesicles on palms Lesions on feet also enlarged red flattened and one or two with tiny central vesicle or pustule March 11th —Lips still swollen and sore Eruption distinctly paler and now presents following appearances Pocks with small central depression vesicle or scab and enlarged circular raised pinkish red areola Whether this is the remains of a collapsed
la is not evident One or
Appearance on palms as
ermis with no raising of
on dorsum of hand
over spots no more
ow feel harder and
uneven and raised not dark General appearance of rash now more like usual varioloid rash at this stage Lips still with dark crusts Tongue unevenly furred April 1st — Patient discharged All the pocks have peeled out Hands and feet rough from presence of unpeeled skin between sites of pocks

In arriving at the diagnosis of varioloid the chief feature relied on at the time was the typical character and distribution of the rash The onset was, no doubt, mild and the development of the rash was somewhat rapid even for modified small pox, but these and other objections were outweighed by the character and distribution—viz , a vesicular, umbilicated rash, chiefly on both surfaces of the hands, wrists, and feet, with markedly "shotty " feel Whilst the appearance of the rash on the second day of its appearance was considered typical of varioloid it must be confessed that the changes that had occurred by the fourth day were a little disconcerting—viz , the enlargement and flattening of the pocks By the eighth day, however (March 13th), the scabs seemed to have regained the appearance of varioloid at the same stage It may be that a larger number of vesicles ought to have been present on the face in order to conform to the typical distribution and it might be objected that one or two of these were large and bleb like

Obviously against the theory of its being modified small-pox was the absence of a severe onset and fever There was certainly considerable constitutional disturbance as shown by the condition of the tongue, lips, &c , and the presence of anorexia. The strongest evidence against is the fact that the patient had an attack of what was taken to be small pox two months before and what is scarcely less significant—that he was successfully revaccinated three months previously There was no known exposure to infection on either occasion A case of small pox of unknown origin was, however, notified in a neighbouring town on Feb 17th and several cases occurred at the latter end of March in the town close to which the school is situated—the origin of which also was untraced The boy was in the habit of going by train to different places with the football team and he travelled from the north through London on Feb 22nd—i.e , 12 days before the rash appeared in the second attack. In short, the possibility of exposure to infection could not be altogether excluded

With regard to the question whether the two attacks were of the same nature, it may be mentioned that the patient himself as well as his mother who helped to nurse him on both occasions, were satisfied as to the similarity of the attacks which had but minor differences From the data available it is probable that the two attacks, whatever their nature were identical Even allowing that the attacks were dissimilar in character, one being, e g , varioloid and one a manifestation of vaccinia, the explanation of the attacks in view of the almost equal immunity against recurrence mutually exhibited by the two infections would be none the less difficult

The alternative diagnosis of the case is that the rash had some connexion with the revaccination As already mentioned the lymph used was part of a large batch obtained at the same time and no abnormal results followed its use in any other case. The maker when applied to wrote that "he d made no alteration in the methods of preparing lymph r many years past and all tubes of a batch were absolutely ke." In the recent literature, however, I have been able to find a case on all fours with this. It differed from e recorded cases of generalised vaccinia in that there was recrudescence at or near the site of the original vesicles d that the rash did not appear until nearly three weeks ter vaccination. Dr. T. D. Acland in his exhaustive icle on vaccinia in Allbutt's "System of Medicine" tes that "vaccinal eruptions are usually characterised by eir temporary duration and irregular distribution and by eir concurrence with vaccination; they were often attended th much irritation, considerable general disturbance, and me pyrexia." "Generalised vaccinia occurs, as a rule, comratively early after vaccination, either one or two days fore or one or two days after the pock at the seat of oculation has arrived at maturity—that is to say, not nerally before the fourth day or after the tenth. The te of its appearance may, however, vary considerably."

During the recent epidemic of small-pox many cases of ccinal eruption have been recorded. Dr. Norman Walker[1] 1901 published and illustrated a case of erythema multime closely resembling small-pox which was somewhat nilar to the case under notice. It was not at first cognised as having any connexion with vaccination, but r similar cases were subsequently seen in which "the ythema appeared in from four to five weeks after the ccination *and in all cases there was a recrudescence of tivity in the vaccination marks.* In the first of these cases e lesions were so like those of small-pox that the patient s very nearly removed to hospital."

Bowen,[2] in September, 1901, published an article on six ses of Bullous Dermatitis following Vaccination and sembling Dermatitis Herpetiformis which were observed Boston from 1895 to 1900. These appear to have been ses of mixed bullous and vesicular eruption of various sizes d *with marked grouping*, the eruption appearing from one four weeks after vaccination and persisting with occanal intervals of freedom for months or years. Itching s usually absent. There was a tendency to grouping out the mouth, nose, ears, the backs of the hands and ists, the ankles, and the feet.

A case of general vaccinia was published[3] last year by eeman in which several "shotty" papules occurred about e left wrist and back of the hand on the sixth day after ccination. On the eighth day all the papules were either sicular or semi-pustular and were umbilicated and multicular. *The palms were quite free as were all other parts of e body except those mentioned.* Another case was described[4] Stewart in which three weeks after revaccination a man veloped numerous large "shotty" papules on the left side his neck which next day covered the entire neck. There ere many vesicles which showed well-marked umbilication. he wrists and forearms, the back of the hands, and foread then became covered with a profuse papular rash. ll trace of the eruption had disappeared in about a week d was succeeded by a slight brawny desquamation lasting few days.

Numerous cases of recrudescence of the vaccine vesicles ithin a few weeks of vaccination have been published and few cases of "latent" vaccinia in which vesicles or scabs rmed on the sites of the original and unsuccessful vaccinaon in one instance two and a half years later, as published by e late Dr. J. W. Washbourn,[5] and in another nine months ter, reported by Dr. J. Mackenzie.[6] Of the recently pubshed cases to which I have been able to refer, the one now nder notice appears to have more closely resembled r. Norman Walker's case than any other. In the latter, owever, the lesions, as shown by the illustration published, eem to have been of various sizes and the umbilication not ery well marked. Moreover, the eruption is reported to ave rapidly disappeared and there is no history of "peelng." In none of the other cases does there appear to have een a well-marked eruption on the palms with the haracteristic "shotty" feel.

The nature of the attacks and the explanation of the ecurrence I must leave to those more competent to form an opinion. It was, however, felt at the time of the second attack, in view of its very suspicious character and similarity to the previous attack, which had passed as small-pox without question, that the isolation of the patient was the most prudent course to pursue.

The case may have an interesting bearing on the connexion between variola and vaccinia and, assuming that the eruption was caused by the vaccination, suggests that vaccinia when introduced into a subject of high susceptibility or of a certain idiosyncrasy may partly revert to its original character. It is an interesting fact that the boy's mother when revaccinated developed a fresh vesicle on the site of the successful vaccination seven weeks later, which suggests an unusual family "receptivity."

As the possibility of exposure to the infection of small-pox can, however, not be excluded that disease must be considered, and although a severe onset with fever is usually deemed essential to the diagnosis of the disease it might be urged that the recent vaccination, whilst not sufficiently protective against an attack of small-pox, was yet powerful enough greatly to modify the symptoms.

Guildford.

THE ILL-HEALTH OF RICHARD WAGNER.

By GEORGE M. GOULD, A.M., M.D.,

EDITOR OF "AMERICAN MEDICINE."

The following quotations are from the Life of Richard Wagner by Glasenapp and Ellis, and from the volumes of Letters to Heckel, Wesendonck, and Liszt. I regret exceedingly that the reproduction here of so large a number of excerpts is necessary. I have omitted many that it seemed possible to spare and not to spoil the clinical picture. Only by careful reading can one get a clear idea of Wagner's sufferings and symptoms and be thus enabled to come to a sound diagnosis of the one malady that resulted in such various and lifelong symptoms.

Richard Wagner was born in 1813. ...... His delicate constitution required peculiar care, for he was already troubled with that irritating form of erysipelas (? erythema or eczema) which recurred at intervals throughout life. ...... Down to his sixth year he had no regular lessons; his mother wished to give him time to pick up strength and would not have him plagued with school work. ...... A pale, slim little chap in short-armed frocks, but unruly enough already—thus these traditions show the tiny Richard. (G., p. 61.)

My good uncle tried his best to put me through some educational training. ...... That I did not profit much by his instruction was, I fear, my own fault. I preferred rambling about the little country town and its environs, to learning the rules of grammar. ...... I often beguiled my uncle into reading me a story that I might avoid working. (1821 or 1822.)

By night they had to suffer for each other, as both were most excitable and fitful sleepers. ...... Cäcilie had plenty to say of her brother's sudden shouts and talking in his sleep, his laughter and tears in the night. (1822–23.)

To roam about the country was his chief delight. (Ditto.)

He ranked among the best pupils in that gymnasium from the first and passed through various divisions and classes with fair rapidity. (1822–27.)

He was plagued with his cutaneous malady even in his school days. ...... Repeated attacks of the kind. ...... An attack would be preceded by depression of spirits and irritability of temper. Conscious of his growing peevishness he would seek refuge in solitude. As soon as the attack was subdued his bright animal spirits returned. (Ditto.)

The refinement and energy of his features and the look of wanness and suffering they wore. (About 1838.)

The prose must be turned into verse and the music composed in a fortnight. ...... His nerves have been so overtaxed that he has "often sat down and wept for a quarter of an hour at a stretch." (1843.)

Constant victimage to a feeble stomach while instrumenting *Tannhäuser.* (1845.)

My whole being had been so consumed with ardour for my task that the nearer I approached its completion the more I was haunted by the notion that a sudden death would stay my hand, so that when at last I wrote its closing chord I felt as joyful as if I had escaped some mortal danger. (1845.)

Lonely walks. (1845.)

Devoted some five weeks from July 3rd to humouring his health as well as his unresting brain would let him. (1845.)

Despite the doctor's warnings against my engaging in any such occupation. (Working at *Lohengrin*, 1845.)

The doctor's [illegible] ny interruption of his present cure th [illegible] the outing. ...... The reason for decl[illegible] f blood to the brain, brought on by his exertions of the past season, had not yet left him. (Ditto.)

Scarcely could he himself say for certain whether his state of health were the cause of his low spirits or they the ground of his feeling so unwell; perhaps it was a little of both. (1846.)

The condition of his health just now is proved by his obtaining a three months' leave of absence "to breathe again as man and artist" in Saxon Switzerland. (1846.)

[illegible] (1847-48.)

[illegible] rk from German mythology, [illegible] uld have undertaken it when [illegible] h is followed by "a period of [illegible] ended with a certain lowering [illegible] the form of a serious illness; [illegible] ression of spirits. ...... He felt [illegible] 1848-49.)

[illegible] out this life, in casting off its [illegible] of 1848.)

Gnawing torments. (1848.)

His warrant describes him as "of medium stature, brown hair, wears glasses." (1849.)

His ancient winter foes return, particularly rheumatism, which this time makes an inroad on his heart. (1849.)

He was thoroughly broken down for the present, what with rheumatism and his recent spell of literary work at high pressure. (January, 1850.)

Feeble, full of pain, unable to sleep, in search of quiet. (February, 1850.)

I'm happy to tell you I've got to the root of my illness; a violence done to my spirit had aggravated my bodily ailments to a dangerous pitch. (February, 1850.)

He means to take a journey southwards for complete recovery of his health. (March, 1850).

I've lost my health, my nerves are shattered. For the present I can live for little more than [illegible] health. 1850.)

Ill, very ill as I was. (Letter to Heine, (1850.)

The last pages of this copy I have written in a mood I can intelligibly describe to no one. Candidly speaking, my only wish is to get the hateful manuscript out of the house. (Of *Opera and Drama*, early in 1851.)

Nine years afterwards Wagner refers to the "fatigue" that had come over him when writing *Opera and Drama*, a fatigue that "so sorely weighed upon his brain," that he calls it an "abnormal state of mind."

[illegible] of working [illegible] am obliged [illegible] ordingly, I [illegible] joy I found [illegible], altogether [illegible] warned me [illegible] out having [illegible] to my impulse and pursued—presumably without a break—what I had just begun. So I came to this hydropathic establishment. ...... Had I gone to my *Young Siegfried* in my present state, perhaps I should have become incurable by next spring. (Autumn, 1851.)

I have become a complete water man. This time I was ten weeks in the hydropathic establishment; only on account of the winter setting in early and with great severity have I given up the cure for the present. However, it was sufficient to give me the clearest foretaste of perfect health, a new and indescribable feeling of comfort, &c. (1851.)

This "water" interlude we may take as a not unwelcome relief in the midst of a more intricate topic. [illegible] however, in the vain attempt to diet [illegible] ince that Uhlig began pressing [illegible] Wagner then replied, "I only [illegible] yet I am far less sanguine than [illegible] ea soon exercised a kind of [illegible] is so far on the road to conver[illegible] the testimony of his younger friend's experience. By Christmas he had commenced to experiment on himself in an amateur fashion: "I, also, am doing a sort of water-cure; besides a sponge-down in the morning, cold water drunk in bed." That does not satisfy the zealot Uhlig; he recommends a "*Neptune-girdle*," which *sounds something like a wet* waistband and makes one shiver at the thought of wintry cold in Switzerland. Wagner valiantly attempts it "I followed your advice about the Neptune-girdle at once. I hope it will suit me. On the whole I feel surprisingly better than last year." (Jan. 20th, 1851.) Two weeks later, however, he has paid the penalty of dabbling "I'm rather unwell. By the advice of a first-rate physician, who also is an [illegible] measures. September 16th Wagner goes to Albisbrunn in the commune of Hausen, on the hills to the south-west of Zürich, too ill to think of any *Siegfrieds* for the moment. On the whole, these ten weeks at Albisbrunn appear to have done him temporary good, but rather as a change of air and scene, a relaxation of mental strain, than in any other way. His humour does not forsake him, and it is here that his gigantic plan matures; but when one reads of the treatment to which he is subjected, one can feel nothing save amazement at the power of resistance innate in his constitution. This is how he describes the "cure," a fortnight ere *its termination*: "*My daily programme now:—1. From half-past* five to seven in the morning, cold pack; then cold tub (Wanne) and promenade; breakfast at eight, dry bread and milk or water [no butter allowed, as he says in another letter]. 2. Short promenade again; then a cold compress. 3. Towards 12 o'clock a wet rub down; short [illegible]. Then dinner in my room to avoid [illegible] other victims, so nasty?]. An hour of [illegible] urs—alone. 4. About 5 o'clock another [illegible] promenade. 5. Hip-bath for a quarter of an [illegible] surely in a [illegible] other com[illegible] t-party till [illegible] ck to bed. [illegible] shall even [illegible] (1851.) [illegible] gined for a [illegible] a sense of well-being such as I had never conceived. My indomitable cheerfulness, &c."

[illegible] the end to baths of but [illegible] ne he has raised their [illegible] 55° F., but mental rest [illegible] t which he describes as [illegible] and water for supper; [illegible] boiled, plain, and meat [illegible] still has at heart.

As for Wagner himself departure from a strict observance of cold water soon was forced upon him by the same consideration that had started it—his health. All through this winter—in fact until next autumn—we hear of one modification or another, in the endeavour to restore a shattered set of nerves, culminating in the lesson of experience passed on to Uhlig next October: "Our water-doctors, one and all, don't know enough about nerve troubles. Constitutions like mine are benefited [illegible] entirely. If [illegible] The same wit [illegible] ood Dresden [illegible] o letter last [illegible]; he has great [illegible] ore sympathetic towards [illegible] not at the same time a [illegible] ...... I am taking a rest [illegible] cure. (December 14th, 1851.)

This winter I shall idle for my health, only sketching as thoughts occur to me. (1851.)

[illegible] nature, an unreservedly [illegible] after *all my art!* There, [illegible] from sleeplessness, with great dejection. (Ditto.)

It is to no water establishment that Wagner goes next spring, as once proposed; his faith in that drastic regimen has been rudely shaken during the last few months. Moreover, "it is quite impossible for me to spend half a year at a hydro." ...... Not long ago he had heard of a certain Dr. Karl Lindemann, a fellow exile, then "working remarkable cures in Paris with a marvellously mild water régime. His specialty seems to be nervous disorders." So he had written Lindemann a detailed account of his symptoms and [illegible] cted period; [illegible] good wine; [illegible] I'm to keep [illegible]

The [illegible] y morning I roam about for tw[illegible] rk. My working time I don't [illegible] s by frequently working five t[illegible] ore. I have finished the entire [illegible]

The [illegible] hat even these few lines set me in a violent commotion. I find that I may be able to do something good, but only on condition that I keep a strict watch on myself, and especially that I interrupt my work often and completely divert my thoughts before going on again. (May, 1852.)

Yesterday I finished my *Walküre* after a month of work ...... once [illegible] ked up: no doubt I work at too [illegible] *Walküre* I always feel as if I had [illegible] anxiety ever increasing toward [illegible] at I should spoil something: my [illegible] I choose of remaining, a perfectly healthy man. If you wretched people would only get a good digestion you would find that life suddenly assumes a very different appearance from what you saw through the medium of your digestive troubles. (November, 1851.

[illegible]. How many [illegible] them to that [illegible]

I am walking capitally, quite strong on my legs; only I'm not contented with my head as yet. The nerves of my brain are hideously out of order—agitation or prostration—never any time true repose. (July, 1852.)

My digestion has been in a very bad way of late. (Ditto.)

Peace I did not find. It's all up; there's no youth left in me; to live stands no longer before me; all my making and doing can now decay. The nerves of my brain!—there's the .)

work but slowly, as everything is an uncommon tax on my brain just now. Only to-day have I finished the MS. of my address on the Performing of *Tannhäuser*. ...... It has taken much out of me and I shall have to try to rest it off. (August, 1852.)

Throughout the whole of these six months we hear one constantly repeated cry of "headache," as if the twofold strain upon the mind were wearing out its organ. At no other period does the physical suffering appear to have been at once so acute and so protracted. Is it a condition normally attendant on the birth of a colossal masterpiece? "My health is none of the best, and although my body looks fairly robust, my nervous system is in a serious state of increasing exhaustion. Through this everlasting life of phantasy without any corresponding reality, the nerves of my brain are so severely overwrought that I can only work by spurts now, and with long interruptions, if I don't mean to become a complete and chronic wreck." (Ditto.)

rushed at last so as to polish everything off, I ruined myself again. Often it's like a sharp knife cutting into the nerves of my brain. Moreover I'm feverishly tired in all my limbs; but if only my head will recover, they also will rapidly improve; on it—that laboratory of the imagination—depends everything. ...... Think of it! even this letter almost knocks me down." (August 30th.)

There cause and effect are plain as can be: the spread of *Tannhäuser*, with all the correspondence involved, has told severely on an excitable system, and the "nerves of his brain"—scientifically speaking, the region round about the optic thalami—must pay the penalty. That "sharp knife" cutting, the "feverish tiredness in the limbs," and the sense of impending evil, are the very symptoms of megrim; the attacks of which, especially if brought on by mental labour, may sometimes be prolonged for several days by successive relapses. (Sept. 5th.)

"Only two lines: I mustn't write, because I can't; that's how things stand with me"; and after barely a dozen lines, "I can write no more. Goodbye." Three days later an equally short letter, so unusual in this correspondence, ends with "That's all I'm able to squeeze out to-day. Don't take it amiss!" (September 8th.)

On the same date a notable letter to Liszt about Raff, Berlioz, and new creations begins and ends as follows: "Unluckily I can't reply to you as I should wish. The nerves of my brain are so racked again that I have had to give up all writing and reading for a while—I might almost say, all mental existence. Every letter—even the briefest—knocks me terribly up, and nothing save the greatest quiet (where and when?) can—or rather, could—put me really right. ...... I can write no more now! Don't be cross with me! My head is nigh bursting! I'll just hurriedly add the warmest farewell I have in my heart." Another three days later: "My head is still bad and all my nerves upset, in consequence of this eternal friction with an invisible land outside. ...... Farewell, I must stretch myself full-length on the divan, to close my eyes" (to Uhlig, September 11th). Next day we have the letter to Roeckel cited a page or two back. A week after that: "I am growing accustomed to the ruin of my nerves; one can always do a little something with them still. ...... To-day is the federal fast-day and for the last week the Föhn has been enough to make one wish one's nerves at the devil." The Föhn is a moisture-laden south wind peculiar to the valleys and lakes of Switzerland, but similar in its general effects to the sirocco so prevalent at Venice, &c. Its humidity would really seem to have eased the writer, however, much as a vapour-bath might; for not only does he indulge once more in a good streak of his pristine humour in this letter of September 19th to Uhlig, but also has important news for us: "My condition isn't a hair's breadth better yet; only I'm gradually accustoming myself to a fresh degradation of my health; I'm accommodating myself to it, and even work a little hour a day now!"

Progress with the poem was by no means break-neck at first, "a little

RICHARD WAGNER (Lenbach).

(By the courtesy of Messrs. Dent and Co., the publishers of Chamberlain's "Richard Wagner.")

From the perpetual expression "the nerves of my brain" ("meine Gehirnnerven"), coupled with the apparent "robustness of body," I should argue [writes Ellis] that the malady was nothing deeper-seated than megrim, *alias* migraine or "sick-headache"; but anyone who has ever been a victim to that scourge, similar in many of its nervous symptoms to "influenza," will recognise the sheer impossibility of mental application when an attack is in full swing. The various forms of dieting, to which Wagner had subjected himself, would only tend to lower the general tone of the nerves, and thus exacerbate the malady. "You people musn't talk theory any more to me just now; it sends me clean crazy. The nerves of my brain!—there's the mischief. I've terribly assaulted them: it's quite possible I may yet go mad!" (August 9th, 1852.)

And so it goes on, with variations of the same complaint (chiefly addressed to Uhlig), at least until the *Rheingold* poem is completed and the greatest load thus discharged from his mind. At first, in fact, it is impossible even to think of poetry. "I've written Heine to-day. My head is not yet clear enough for working." (August 11th.)

"Unfortunately I'm getting on very slowly [with the *Tannhäuser* Guide], as all manner of work tries my head uncommonly just now." (August 14th.)

"If my head were but better! With that cursed brochure, which I hour a day." Nor even every day, for a fortnight later the intimation to Liszt runs: "My nerves are still none of the best, yet I have begun to work a short hour a day at my poem again, off and on." *(October 3rd.)*

"I shall tell you nothing about my work; it's going slowly, but well! Fare well and healthier than me. I shall shortly go crazy!" (Oct. 5th)—a repetition of the fear expressed two months ago. Before a week is out, the poem has to be laid aside. "That I am able to write y

not answering at once. "That sort of letter always takes a deal out

Partly due to the fateful lesson of the work itself, the greater share of this lack of elation must be assigned to the same cause that had impeded the poem's progress: excessive nerve fatigue. The letter that announces the event to Uhlig—and a very long letter it is, as a rest is being taken—for the most part consists of reflections on death and diet:

the utmost comfort,
I'm assured by many
observe this diet, and
... Simple foodstuffs are not for such as you and me: we need the complex substances that offer the utmost nourishment with the smallest demand on the power of digestion. *Our rule should be to eat often, little and good, at the same time to avoid all great exertion,*

even in bodily movements, but be careful for comfort and agreeable rest." It is the valetudinarian's gospel; but, when the invalid happens to have such an "object in life" before him as the composition of a *Ring der Nibelungen*, it becomes his absolute duty to take care of himself for sake of the world.

The same complaint of nerve-fatigue that formed a running accompaniment to the *Rheingold* poem ushers in the revision of the two *Siegfrieds*: "I must stop; my head's getting bad." (November, 1852.)

Uninterrupted work has again strongly affected me and the nerves of my brain are so overwrought that even these few lines put me in a state of violent excitement, wherefore I must ask you not to be angry if I make them very short. (1852.)

I feel that I am still capable of doing good things but only by keeping very strict diet, and especially by frequently interrupting my work and entirely diverting my thoughts before going on again. (Ditto.)

The *Valkyrie*, the poem of which I finished on July 1st, I wrote in four weeks; if I had spent eight weeks over it I should now feel better. In future I must adopt this course. (Ditto.)

Unfortunately I cannot reply to your letter as I should like to do; the nerves of my brain are once more in a state of great suffering, and for some time I ought to give up all reading and writing, I might say all mental existence. Even the shortest letter wearies me terribly. ...... I only wish to explain to you why it is that to-day I must limit my communication to stating briefly what is absolutely necessary. ...... The work has been a perfect torture to me. This eternal communication by letter and print is terrible to me. (Ditto, September, 1852.)

I am going from bad to worse every day and lead an indescribably worthless life. ...... Perhaps you will soon be rid of me. (November, 1852.)

My terrible melancholy. (Ditto, January, 1853.)

In case I should die during the work. (Ditto, February, 1853.)

How long I shall endure this terrible joylessness I cannot tell. About the middle of last month I was on the point of succumbing and thought that I should soon have to follow my poor Uhlig. I was persuaded to call in a doctor, and he, a careful, considerate, and conscientious man, takes much trouble with me. He visits me nearly every other day and I cannot but approve of his treatment. Certain it is that if I do not recover it will not be *his* fault. ...... For me there is no salvation but *death*. Would that it found me in a storm at sea, not on a sick bed! (Ditto, Feb. 11th, 1853.)

I can only live in extremes—great activity and excitement and—most perfect calm. (March 4th, 1853.)

My nights are mostly sleepless. (March, 1853.)

Whether the cure has been of any use to me the future must show, but upon the whole I am not inclined to repeat it. (Ditto, at St. Moritz, July, 1853.)

The foolish man wants to hear something from me about his book, but as soon as I bend my head a little towards *theory* the nerves of my [illegible]. I feel quite ill. (Ditto.)

[illegible] men of our sort should not write at [illegible] nd have great difficulty in persuading myself that it must go on like this and that it would not really be more moral to put an end to this disgraceful kind of life. ...... To cure my sick brain the doctor has prevailed upon me to give up taking snuff altogether; for the last six days I have not taken a single pinch, which only he can appreciate who is himself as passionate a snuff-taker as I was. Only now I begin to perceive that snuff was the solitary real enjoyment that I had occasionally, and now I give that up too. (August, 1853.)

I am back again in Zürich, unwell, low-spirited, ready to die. ...... At Genoa I became ill, &c. (Ditto, September, 1853.)

I have many things to tell you but my head is burning. There is something wrong with me; and sometimes with lightning-like rapidity the thought flashes through me that it would be better after all if I died. (Ditto, December, 1853.)

Rheingold is done, but I also am done for. (Ditto, January, 1854.)

I went to this music with so much faith, so much joy; and with a true fury of despair I continued and have at last finished it. ...

With my terrible care my violent nervous disorder has also returned. ...... "With myself things are going from bad to worse each day; 'tis an indescribably good-for-nothing life I'm living! Of actual enjoyment of life I know absolutely nothing; to me the 'pleasure of life, of love' is purely a matter of imagination, not of experience. So my heart has had to pass into my brain and my life to become a mere artificial one; only as 'artist' can I still live; into the artist has my whole 'man' been resolved. If I take account of the wretched state now normal to me, I cannot but deem my nerves ruined; strange to say, however, these nerves do me the most wonderful service when put to it, when sufficiently fine incentives come to me; then I have a clearness of vision, a sense of pleasure in perceiving and creating, such as I never knew before. Ought I to call my nerves ruined then? I cannot. Only I see that—in the way my nature has developed—its normal state is exaltation, whereas the ordinary calm is abnormal to it."[1] (January, 1854.)

This having to make a clean-copy kills me. ...... The continual writing tires me to such an extent that I feel quite ill and lose the inclination for real work. (March, 1854.)

This dislike of work (composition) is the worst feature of all. I feel as if with it eternal night were closing around me. (May, 1855.)

My frequent nervous headaches. (Letter to Wesendonck from London, 1855.)

My mental disharmony is indescribable; sometimes I stare at my paper for days together,[2] without remembrance or thought or liking for my work. (Letter to Liszt, July, 1855.)

After much trouble the first half of the *Valkyrie*, including a clean copy, has got finished. ...... For the last week indisposition has prevented me from doing anything and if this goes on I almost doubt whether I shall be able to finish this work from the sketches. (Ditto.)

I am making a tentative effort to rise from the sick bed on which I have lain again exactly three weeks ...... I have suffered from continual attacks of erysipelas of the face. (December, 1855.)

I am again, or rather still, unwell and incapable of anything (January, 1856.)

I am continually at war with my health and fear a relapse at any time.

I am waiting to see what my health will do; my doctor wants to send me to some watering-place, but to this I will not, and cannot, agree. (Ditto, during 1856.)

Again on a sick bed. To-day I am scarcely recovered and fear another relapse. ...... If I could only be well again!" ...... Another attack of erysipelas. ...... This abominable illness has brought me very low ...... The slightest disorder of my stomach immediately affects my complaint. (Ditto.)

In that terrible month of May I was able only to look at your scores with a tired eye and as through dark clouds.

My only care now is the perfect recovery of my health.

God knows I castigate my flesh by this cure ...... placed myself under Dr. Vaillant who conducts a hydropathic establishment here. ...... I feel sure of being completely cured of my ailment which, after all, was caused by nervousness. ...... During my cure I must not think of doing any work. (July, 1856.)

My catarrh has developed so that I may hope it will rid me of my usual winter illness. My health, too, is once more so bad that for ten days after I had finished the sketch for the first act of *Siegfried*. I was literally not able to write a single bar without being driven away from my work by a most alarming headache. Every morning I sit down, stare at the paper, and am glad enough when I get as far as reading Walter Scott. The fact is I have once more overtaxed myself, and how am I to recover my strength? With *Rheingold* I got on well enough but the *Valkyrie* caused me much pain. At present my nervous system resembles a pianoforte very much out of tune. (January, 1857.)

Imagine that for a week and a half I have not been able to move from my chair. This illness was just what was required to finish me up. I had just resumed my work a little after a gastric and nervous indisposition, when I was obliged to give in again. (December, 1858.)

The weather is bad; I am absolutely alone and seldom in the right mood for work. So I drag on amidst mists and moods.

My health still gives me much trouble.

My health is ruined for want of life and action.

The last act of this child of sorrow (*Tristan*) is now on the verge of "to be or not to be"; a slight pressure of some spring of the vulgar fate, at whose mercy I am, might kill this child at the very moment of its birth. Everything with me depends now upon the turning of a hand; there may be a way and there may be a stoppage, for I, my Franz, am in a bad way. ...... How miserably weak I feel as a musician. I know in my heart that I am an absolute blunderer. You ought to watch me when I am at it; now thinking "it must do after all," then going to the piano to puzzle out some wretched rubbish and giving it up in a state of idiocy. (Ditto, 1859.)

I feel as if I should break down in sight of the goal. Once at least every day I look at my book (*Tristan*) with a right good will, but my head is waste, my heart empty, and I stare at the mist and the rain clouds, which, ever since I have been here, have debarred me even from the chance of shaking up my stagnant blood by pleasant exertions ...... work alone is to help me, but who is to help me to the possibility of work? (Ditto, 1859.)

I have been severely ill these four weeks and my recovery is scarcely noticeable. I am still extremely weak. ...... I begin to perspire, and can write no more. (1859 *passim*.)

I am very slowly regaining my strength. What impedes my recovery, and indeed makes it impossible for the present, are the extraordinary exertions and excitements to which I have to expose my health, which is gradually coming back to me. ...... The proofs of *Rheingold*, which Messrs. Schott would have liked so much to have published at Christmas, have been lying on my table for seven weeks without my being able to make any progress with them. (Letter to Liszt, 1860.)

I seek rest and happiness no longer, but only breathing-space for new labours, from which *I* reap the least enjoyment. (Letters to M. v. M., 1860.)

His exertions brought on a serious illness which threatened to develop into brain fever. (Ellis, 1860.)

[illegible], the doctor's orders, with all kinds of [illegible] to Wesendonck, 1860.)

[illegible] s. (Ditto.)

A night slept through from 1 to 8 A.M. is an ideal happiness to me which I only taste as an utter rarity. (Ditto, 1861.)

...... travelled to the South of France by his doctor's advice. (Ditto, 1865.)

A doctor, whom I have consulted, recommends me Cannes. (Letter to E. W., 1864.)

I was hindered by terrible sickness from continuing my journey that day. (Ditto, 1861.)

"People often call me irascible when I am simply ill," he used to say. (Fink.)

From 1866 to 1872 at Triebschen Wagner displayed a creative activity which was simply incredible. ...... Happiness has no history. The six years at Triebschen were the happiest of his whole life. (Chamberlain.)

Truly all our politics, diplomacy, ambition, feebleness, science—unfortunately too all our modern art—all these parasitic growths upon our life have no other soil upon which they flourish than our ruined stomachs. [He seems to have thought vegetarianism "the key-stone of regeneration."] We must abstain from meat and alcoholic drinks. [Only adopted for a while.] (Letter to Liszt.)

I shall devote next summer to nothing but the possible recruiting of my health—for which, on account of the wearing and increasing pains in my abdomen, I think of taking a very protracted course of waters at Marienbad and so on. If I find myself restored to health ...... In one of my perpetually sleepless nights I have tried to gain a little ease. (Letters to Heckel, 1876, p. 99.)

In 1878 a medical examination showed amyloid degeneration of the liver, spleen, and kidneys. (Ellis.)

I am at the commencement of a course of waters, which may be very prolonged. (To Heckel, 1879, p. 118.) He had "a serious illness" in 1880. [Serious organic diseases at this time having set in.]

Only to-day do I write you, as this mournful business had to be postponed because my health is such that my dear wife was afraid even to impart to me the news of the sudden death of your father. (Ditto, 1882, p. 127.)

During the last few months there was much dyspnœa, especially after meals, but he was also busy writing several hours every morning. (Ellis.)

---

[1] Compare this with the experience of Carlyle (vide p. 70 of Biographic Clinics) who in the same way and from the same reason had to work "in a red-hot element," "with his heart's blood in a state of fevered tension," &c.

[2] Compare similar expression by Carlyle.

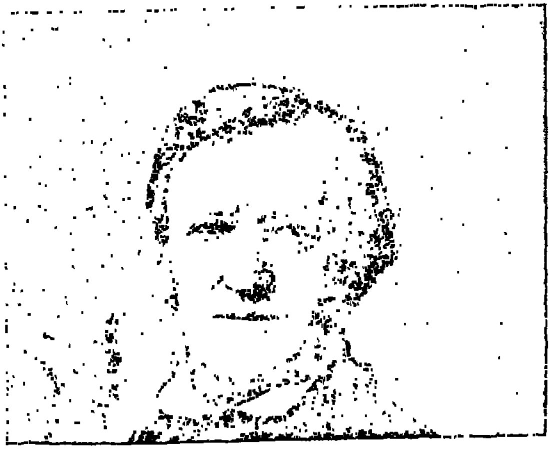
He died Feb. 13th, 1883. The necropsy showed a much dilated stomach, internal inguinal hernia, much dilated heart with fatty degeneration.) Death occurred directly from rupture of the right ventricle.[3]

Headache, "sick headache," "dyspepsia," "nervousness," melancholy, insomnia, indescribable suffering—these were some of the more prominent symptoms that, in various mixtures, rendered so miserable the lives of de Quincey, Carlyle, Darwin, Huxley, Browning, Spencer, and Parkman. Some of them had some of the symptoms all of the time, some had all of them some of the time. Wagner had all of them all of the time. All of them found these symptoms exactly proportioned to the amount of reading and writing that was attempted, and when the eyes were driven to their unphysiological function the symptoms increased in intensity until life itself was threatened either by the disease or by the despair of the patient. Darwin and Wagner kept up the sad belief in the therapeutic uses of hydropathy all their lives. Carlyle and Parkman tried it, but soon perceived the folly of it. Every one of the eight learned that the only cure or relief to be found consisted in stopping reading and writing—i.e., in the non-use of the eyes at near range, and in out-of-door exercise.[4] In addition to all the affections mentioned, Wagner had the mercuric artistic temperament, endured the bitterest mental anguish from the non-recognition and hate of his musical works, and he was poor. He also suffered all his life from an intercurrent affection, erysipelas, which is a disease dependent upon denutrition. There can be nothing in medicine more certain than that eyestrain causes denutrition, and nothing more certain than that Wagner had terrible eyestrain.

It should be noted that Wagner was a "delicate boy," "a pale slim little chap," needing to "pick up strength," not profiting by instruction, liking others to read to him, "preferred rambling," "roaming about the country," an excitable and fitful sleeper, shouting and talking in his sleep, &c. But the intellectual and keen mind soon realised the sense of responsibility, and the boy picks up his school work equal to the best from his ninth to his fourteenth year, but at 25 years of age his features have "the look of wanness and suffering." All of this is an excellent description of children who suffer from eyestrain and can be duplicated from the case records of ophthalmologists many times.

At about 30 years of age an excess of writing work overtaxed his nerves so much that he "often sat down and wept for a quarter of an hour at a stretch" and he was a constant victim of a feeble stomach. At this time an extreme amount of work with his pen brought on the idea of sudden death which in the same circumstances reappeared many times during his life and threatened to drive him to suicide. The medical man warned him against work, fearing the "determination of blood to the head," and ordered leaves of absence for three months, &c.[5]

FIG. 3.



RICHARD WAGNER.

(From Rubenstein's arrangement of the vocal score of *Tannhauser.*) This photograph probably formed the basis of Lenbach's realistic drawing.

[illegible] a long life of work. I am very sensitive and irritable, quickly becoming feverish and despairing, but never really ill, and [illegible] s." This [illegible] his eyes [illegible] plaint, in [illegible] find in his biographical reading constant proofs of the rôle of eyestrain which have hitherto escaped notice. For instance, of Adolf, the uncle of Richard Wagner, a man devoted to literary work, I find the following suggestive paragraph: "His bodily strength now commencing to fail with the advent of maladies brought on by the sedentariness of his occupation, Adolf resumed his favourite exercise of old, long walks, which he did not abandon until a year or so before his death." "For a year and a half or

[illegible] who [illegible] was the [illegible] of the [illegible] whose life

With each increment of added accommodation-failure things go from bad to worse every year, until at the age of 35 years Wagner feels "too old" for undertaking his greatest art-work. Depression and suffering, "brokendownness," always follow near work and especially so in winter, his "mortal enemy," when vitality was always lowered, because there was more confinement in the house and hence more reading and writing. A hundred statements grow ever clearer and clearer that writing and reading are becoming more and more impossible, produce greater and greater suffering, and that after each opera, poem, or literary work the ill-health is more tragical. He cannot even undertake "to make a copy"; music-writing is "natural and easy" and yet at the very beginning of such labour he is warned that he will undermine his health. Finally, "the nerves of his brain are so overwrought that the writing is reduced to two hours a day, instead of five or six as formerly, and the writing of a few lines of a letter sets him in violent commotion." As all ophthalmologists instruct their patients, so Wagner found by experience that he had often frequently to interrupt even his two hours a day of eye-work. Every job of composition or writing "takes much out of him" and he has "to rest it off." Headache, sleeplessness, the "working by spurts," "with long interruptions," a hundred such expressions occur, and the fear of death, the longing for it, or the resolve to seek it, is constantly reappearing. Hundreds of such expressions as the following could be gathered: "If my head were but better"; "I shall go mad"; "the sharp knife cutting into the nerves of my brain"; "feverishly tired in all my limbs"; "even this letter almost knocks me down"; "I *mustn't* write, because I can't"; "my head is nigh bursting"; "every letter knocks me terribly up"; "the nerves of my brain are so racked that I have had to give up all writing and reading for awhile"; "I even work a *little* hour a day now"; "a short hour a day now off and on"; "I shall shortly go crazy"; "letter-writing, I am now convinced once for all, severely taxes me, and you therefore may flatter yourself if I manage to fill even this sheet of paper"; "completed my work very much exhausted"; "from noon till bedtime I never write another line"; "writing a longish letter prevents all other work that day"; "I must stop, my head's getting bad"; "even these few lines put me in a state of violent excitement"; "I ought to give up all reading and writing"; "even the shortest letter wearies me terribly"; "my work has been a perfect torture to me"; "this eternal communication by letter and print is terrible to me"; "my terrible melancholy"; "my nights are mostly sleepless"; "as soon as I bend my head toward theory the nerves of my brain begin to ache violently and I feel quite ill"; "truly writing is misery, and men of our sort should not write at all"; "the *Rheingold* is done, but I also am done for"; "this having to make a clean copy kills me"; "I begin to perspire and can write no more"; "the proofs are lying on my table for seven weeks"; "farewell, I must stretch myself full length on the divan and close my eyes." This poor patient may be excused for not recognising the simplest conclusion that the eyes were at the bottom of all this suffering. With difficulty, however, may the medical men of his day be excused, and there is no excuse for the most cruel of crimes, the brutal obstinacy which to-day makes a few ultra conservative physicians, and even some careless ophthalmologists, deny that such symptoms in thousands of patients are due to eyestrain and are daily cured by its correction.

Even to-day men are wet-packed, as Wagner and Darwin were all their lives, for astigmatism. The silly superstition that there is any mysterious virtue in cold water has been, and is still, filling the pockets of quacks and exhausting the vitality of numberless patients. Let one with open mind read the hydropathic histories of Darwin and Wagner and not have his gorge rise with indignation. The sole good done by this nonsense, to offset the enormous, evil was that while shivering in dripping sheets the poor eyes and brain could not be doing reading and writing. Hence the little seeming good, the raised hopes, and the succeeding despair when ocular strain was again resumed.

Wagner's clearest symptom was "sick headache"; migraine, megrim, hemicrania, nervous headache or bilious headache are other names for this terrible affliction. It causes a large number of other symptoms and is itself of an infinitely varied type, according to the kind of near work required and the kind of organism of the patient. I have had thousands of patients with this disease and 99 out of every 100 were cured by spectacles. That sick headaches often disappear at the age of from 50 to 60 years is due solely to the fact that presbyopia makes eye-strain impossible. That the wrecked nervous system may sometimes go on exhibiting the symptoms after the exciting and direct cause has ceased is a truism not only of medicine but of common sense. "From 1871 onwards he had an immense amount of business to transact," writes Mr. Ellis to me, "in connexion with the building of the Bayreuth theatre, &c., but of specific complaint of headache I nowhere find a trace in the later years." All the symptoms of Wagner's functional diseases ended with the establishment of presbyopia. The sick headaches, the melancholy, the fear of death, the resolve to commit suicide, the nervousness and the insomnia ended then, not because the King of Bavaria came to the rescue of this greatest of musical geniuses, not because the wrong wife went and the right one came, not because success and popularity arrived, but because his wife acted as amanuensis, &c., and therefore he was not driven to the maddening eye-labour, and because presbyopia prevented the suffering which was the result of the least of such labour. One eye at last went out of function and this helped also to establish relief.

In Wagner's warrant he is described as "wearing glasses." Outside of that simple statement none ever seems to have seen him doing so or to have spoken of the fact. Mr. Ellis has proof that seems to him pretty good that he did not wear them. It is of no consequence whatever. Any spectacles he could get would not have neutralised his eyestrain. Were he living to-day he would in all probability not find any ophthalmologist or physician in Germany that would help him or care to help him in the one possible and effective way. There are a hundred ophthalmologists, nerve specialists, and general physicians, even in the United States, who would smile scornfully at the idea that a patient having Wagner's symptoms could be cured by the correction of his ametropia. Fortunately, there are hundreds of others who know the truth, and better, who practise it.

All through the latter part of Wagner's life he had one symptom, one of those which physicians call "objective," one that is alluded to, so far as I know, by no written word. In speaking to a great musician who knew Wagner, I mentioned this symptom, when he broke in with, "Of course! I had often observed the fact, but thought nothing of it." This symptom, which all of his physicians also ignored, comes out in most of the later photographs and the portraits, especially in those of Lenbach the realistic painter. The left eye is turned out and up. (Consult the portraits herewith reproduced.) Some American ophthalmologists call this defect "hyperexophoria." In the effort to drag the eyelid away from, and above, the pupil of this eye, it will be noticed that the forehead is arched and wrinkled in concentric curves—an appearance noticed in many such patients. In the pictures in early life this combination of heterophoria and strabismus is not shown because it did not exist. It had been overcome by strain, if it existed, and the strain had produced its effect.[6] Some of the later photographs do not show the outward and upward turning of the eye, a fact that demonstrates the temporary ability to overcome it by intense effort of "fixation" or concentration of the attention. This turning of the left eye upward and outward is, as ophthalmologists know, a result of ametropia and especially of astigmatism and anisometropia. It was a relief of eyestrain, an effect rather than the cause of it—a fact that the "graduated tenotomists," the cutters and snippers of eye muscles, forget.

A bungling newspaper headline of a review was *The Eye of Genius*—as if geniuses had a peculiar sort of eye defect. The geniuses are few, the slaves of civilisation millions. Even Wagner and Carlyle and de Quincy, as poor as they were, could stop near-range ocular work when they were compelled to do so or limit it to "a little hour" a day. Sewing-women,

---

same cause. In his melancholy and suffering his greatest danger had been suicide. Great nerve specialists had drugged him to stupor or had "rested" him nearly to death. Luckily he escaped the hydropathist and Christian Scientists. On this same day I also received bitter criticism from a great ophthalmic surgeon that I am an exaggerator and hobby-rider. A great rest-cure man does not even acknowledge the receipt of a complimentary copy of "Biographic Clinics." And so on.

[6] Even in th [illegible] ılar defect is not always shown, chiefly, [illegible] by intense effort to overcome it and to s [illegible] n a letter to Dr. Pusinelli, Wagner says that the constraint and mechanical preparations for being photographed rendered it very difficult to procure a faithful likeness of his "so changeable expression." Whether "fixing" with both eyes or with but one would make a great difference in the expression. The vertical wrinkles between the eyes are also proof of eyestrain.

typewriters, clerks, many students, teachers, all poor handi craftsmen and women cannot ,
or ten hours every day and
defects as the ' geniuses '
fore greater than to the geniuses There is no greater cruelty, no greater crime against humanity than this of non recognition and scorn of eyestrain

This evidence presented by the portrait painter and the photographer of Wagner would not be needed by the expert ophthalmologist to prove the fact of the cause of his lifetime of awful misery It adds the demonstration needed to convince general physicians and intelligent laymen Many thousands of such non medical persons who have been cured of appalling sufferings like those endured by Wagner would not need such a proof The mere reading of the list of quotations I have gathered would make them shudder to think of their own past experience Multitudes of others still await the finger of a divine science upon their eyes But that touch must first come to the eyes of physicians, too many of them still blind by prejudice and tradition

THE ESTIMATION OF FREE HYDROCHLORIC ACID IN THE GASTRIC CONTENTS

BY C E HAM, M B LOND ,
AND
J J R. MACLEOD, M B ABERD
(*From the Chemical Laboratory of the Pathological Institute, London Hospital*)

IN 1889 F A Hoffmann[1] described a method for the estimation of uncombined hydrochloric acid in the gastric contents This method depends on the catalytic power of the free acid in producing inversion of cane sugar, and was undertaken on the suggestion of Professor W A Ostwald Hoffmann published some further papers[2] on his application of the method to gastric contents, but otherwise it does not seem to have been employed for this purpose O Cohnheim[3] in 1896 also used the method to determine the combining powers of proteoses and peptones for hydrochloric acid. As the other methods employed in clinical medicine for the *estimation* of the free hydrochloric acid are very inaccurate for small quantities of undiluted gastric juice and are, moreover, very difficult of application, we thought that it might be of service to repeat Hoffmann s work and to see whether the method could not be so far simplified as to make it applicable for clinical workers without at the same time affecting its accuracy Before recording our results we had hoped to obtain records of the analyses of vomits from various gastric diseases, but owing to our having to suspend the work for some time we have thought it desirable to publish our experiences with the *method* at present the more especially since we have found that it can be materially simplified without affecting its accuracy We hope that it may prove useful in the hands of clinical workers

THE PRINCIPLE OF THE METHOD

The rapidity of the inversion of cane sugar by free acid is proportional to the amount of the free acid present By comparing, therefore, the amount of inversion produced in a cane sugar solution by adding gastric juice to it with the amount of inversion produced in a cane sugar solution containing a known amount of free HCl—both solutions being incubated at the same temperature and for the same length of time—we can accurately determine the amount of *free* HCl in the gastric juice[4]

To measure *accurately* the amount of free acid in the unknown solution by comparing it with a known solution all the conditions which influence such a chemical reaction must be constant in the two solutions As this is difficult to attain, advantage is taken of Wilhelmy s law for the course of such reactions Expressed in common logarithms this law may be expressed by the following formula $C = \log A - \log (A - x)$, where C = a constant representing the relative catalytic power—i e., the nature and quantity—of acid present, A = the amount of cane sugar originally present, and x = the amount of cane sugar which has undergone inversion in a given time

With regard to A, the quantity of sugar contained in an optically active solution is proportional to the angle through which the plane of polarised light is rotated Therefore the total number of degrees through which cane sugar when completely inverted changes in rotation is directly proportional to the amount of sugar which the solution contains, or, in other words, A = the total number of degrees through which change of rotation takes place on complete inversion The value of A could therefore be found by allowing a solution of cane sugar of known dextro rotatory power to incubate at a certain temperature in the presence of a strong acid until it was completely inverted and then noting how much laevo rotation was produced A would thus equal the amount of rotation of the cane sugar solution before inversion plus the number of degrees of lævo-rotation after inversion This process, however, would be tedious and, according to Hoffmann A can be more easily obtained by multiplying the initial number of degrees which the cane sugar solution is capable of rotating polarised light to the right by 0 4416 for 0° C , and for every degree Centigrade above 0° 0 00506 must be subtracted from that factor, the product of this being the amount of lævo rotation which would be produced by complete inversion. The original dextro rotation plus this figure gives the total rotation and represents the value of A We have made several experiments to test the reliability of this factor and have found it to be perfectly accurate. In the same way x is proportional to the difference of the rotatory number at the beginning and end of the experiment—e g , a certain solution had a dextro rotatory power of 50 before inversion, and after inversion this was 45, then $x = 5$

From the above data we are thus able to find the value of C by substituting the values of logs of A and $A - x$ in equation

$$C = \log A - \log (A - x)$$

Now let us suppose that C represents the constant for the solution containing the unknown value of HCl. Then in order to find out the amount of free HCl in the gastric juice (which is the unknown solution) we must compare it with the constant which we will call C', of a solution of cane sugar to which a known quantity of the same acid—viz , HCl—has been added, and by incubating both solutions at the same temperature and for the same time the relation of C to C' must correspond to the *amount* of acid present. Suppose d = the amount of acid present in the known solution then the amount of acid present in the unknown solution can be easily found by the following simple formula ,

$$A = \frac{C}{C'} \ d \quad (A = \text{HCl in the unknown solution})$$

The method as employed by us is as follows The stomach contents are removed by passing a stomach tube two hours after a breakfast consisting of two eggs two cups of coffee, two pieces of toast and a large slice of bread and butter (We chose this meal as it approached the normal more nearly than one of the test breakfasts usually given in clinical investigations) The gastric contents, undiluted with water, are heated to near boiling point in order to destroy the pepsin , otherwise proteolytic digestion would proceed during the incubation which follows and the resulting proteoses and peptones combine with the free HCl, since as Cohnheim[5] has shown the combining powers of these is markedly stronger than is that of less hydrolysed—e g native—proteids The vomit is then allowed to cool and is quickly filtered through an ash free filter paper, the ash of ordinary paper being capable of taking up some of the free HCl.[6] If dark in colour charcoal must not be used to decolourise the vomit, for it readily absorbs the free HCl.[7] Portions of the filtered vomit measuring five cubic centimetres each are then placed in four small Erlenmeyer's flasks (100 cubic centimetres capacity). To three of these are added 10 cubic centimetres of a saturated solution of cane sugar[8] and to one of them, also, a crystal of sodium acetate. The sodium acetate is added to absorb the free HCl, this preparation serving as a control for the detection of other inversive agencies in the vomit. All the four solutions are diluted with water to 20 cubic centimetres. The fourth flask, containing only five cubic centimetres vomit and 15 cubic centimetres water, serves as a control for any inversion of maltose which might take place. To a fifth flask are added a known quantity of $\frac{N}{100}$ HCl and 10 cubic centimetres cane-sugar solution. Its volume is likewise brought up to 20 cubic centimetres. The rotatory power of each of the solutions is then measured. For this purpose we have used a saccharimeter manufactured by Schmidt and Haensch and graduated so that 100 divisions of the scale correspond to a cane-sugar solution containing 26·048 grammes of sugar per 100 cubic centimetres and examined in a tube 200 millimetres in length (Ventzke scale). Any other scale will, however, serve equally well provided that for each determination the same scale is employed. The same applies to the tube which may be of any length provided the same tube is always employed. The scale should read to one-tenth of a degree. The solutions are then incubated at 37° C. for about 24 hours. We employ this temperature as at higher ones (as employed by Hoffmann) it is most probable that a certain amount of dissociation of HCl takes place from its combination with proteid,[9] thus rendering the results for free HCl too high. The solutions after incubation are quickly cooled so as to stop further inversion and are again examined in the saccharimeter. We have taken our saccharimetric readings always at a temperature of 15° C., at which the factor for finding the value of A is 0·3657.

[1] reien Salzsäure im Magensaft No 46

[2] o im Magensaft Centralblatt für Klinische Medicin 1890 No 29 Also Schmidt's Jahrbücher Band 233 S 263

[3] Zeitschrift für Biologie Band 33 S 493

[4] This action of free HCl in inverting cane sugar is due to its being a catalytic agent and it will accelerate a large number of other chemical processes in virtue of this power Cane sugar is chosen as the body for the HCl to act on because of the ease with which the chemical change can be measured A solution of cane sugar rotates the plane of polarised light to the right the amount of rotation depending on inversion, ore rotates t to that —dually gets less and less as the HCl acts on it and if left long enough it ultimately becomes lævo-rotatory

[5] Zeitschrift für Biologie, Band xxxiii S 43.

To make the method of calculation clear we will give an actual determination in detail. (The stomach contents in this case were somewhat diluted with water, a glass of water having been taken just before the stomach-tube was inserted). The following solutions were prepared: (*a*) five cubic centimetres of vomit, 10 cubic centimetres of cane-sugar solution, and five cubic centimetres of water. Rotation at beginning + 34·9; at end[10] + 30·5. (a^1) Same as (*a*) (to serve as control). Rotation at beginning + 34·65; at end + 30·2. (*b*) Same with crystal of sodium acetate. Rotation at beginning + 35·0; at end + 35·0. (*c*) Five cubic centimetres $\frac{N}{100}$ HCl, 10 cubic centimetres of cane-sugar solution, and five cubic centimetres of water. Rotation at beginning + 34·9; at end + 26·0. (*d*) 10 cubic centimetres of gastric juice and 10 cubic centimetres of water. Rotation at beginning + 2·5; at end + 2·6. Since there is no inversion either in (*b*) or (*d*) we may proceed at once with the calculation.

$$C = \log.\ A - \log.\ (A - x)$$

$$\begin{aligned} A &= 34{\cdot}9 \times 0{\cdot}3657 = 12{\cdot}763 + 34{\cdot}9 = 47{\cdot}66 \\ x &= 34{\cdot}9 - 30{\cdot}5 = 4{\cdot}4 \text{ and} \\ (A - x) &= 47{\cdot}66 - 4{\cdot}4 = 43{\cdot}26 \end{aligned}$$

The common logarithm of 47·66 = 2·6781
and of 43·26 = 2·6361

$$\therefore\ C = 2{\cdot}6781 - 2{\cdot}6361 = 0{\cdot}0420$$

We must now find the value of C'.

In this case:

$$\begin{aligned} A' &= 34{\cdot}9 \times 0{\cdot}3657 = 12{\cdot}763 + 34{\cdot}9 = 47{\cdot}66 \\ x' &= 34{\cdot}9 - 26 = 8{\cdot}9 \text{ and} \\ (A' - x') &= 47{\cdot}6 - 8{\cdot}9 = 38{\cdot}7 \end{aligned}$$

The common logarithm of 47·66 = 2·6781
and of 38·7 = 2·5877

$$\therefore\ C' = 2{\cdot}6781 - 2{\cdot}5877 = 0{\cdot}0904$$

The amount of acid in (*c*) is five cubic centimetres $\frac{N}{100}$ HCl, which equals 0·001825 gr. HCl.

∴ The amount of acid in the vomit is

$$\frac{0{\cdot}001825 \times 0{\cdot}0420}{0{\cdot}0904} = 0{\cdot}000847 \text{ gr. or } 0{\cdot}01694 \text{ per cent.}$$

This calculation, although at first sight it may seem laborious, really takes very little time provided one can make use of the logarithmic tables. We have, however, found that an *approximate calculation* can be made by a very much simpler method. To use this simpler calculation it is necessary that the original rotatory power of all the solutions be as nearly as possible the same and, of course, that they be incubated for exactly the same period of time. The amount of HCl in the vomit can then be obtained by multiplying the number of degrees of inversion—i.e., x—of the unknown solution by the amount of acid which is contained in the known one and dividing the product by the amount of inversion produced in the known solution. Thus, taking the above example, inversion produced in unknown solution = 4·4; inversion produced in known solution (containing 0·001825 gr. HCl) = 8·9.

$$\therefore\ \frac{4{\cdot}4 \times 0{\cdot}001825}{8\ 9} = 0{\cdot}00090, \text{ or } 0{\cdot}0018 \text{ per cent.}$$

The following figures will show the approximate accuracy of this simpler method:—

Free HCl contained in 100 parts Vomit.

I.—By Hoffmann's method.	II.—By simple equation.
0·0518	0·052
0·058	0 056
0·086	0 090
0 050	0 040
0·066	0·061
0·017 (diluted juice).	0 018

Proofs of the accuracy and delicacy of the method.—The inversion test is a very delicate one for the detection of free HCl. In this respect it is even more delicate than the ordinarily used colour tests. The following table gives the results of one of the experiments we carried out to demonstrate this:—

Amount of HCl in 20 cubic centimetres.	Inversion test.	Gunzburg's test.	Di methyl amido azo-benzol.
0·000365 gr.	Measurable rotation in 24 hours at 60° C.	Negative.	Negative.
0·00073 gr.	Well-marked rotation.	Very faint.	Faint.

The results depicted in this experiment we have obtained in a large number of controls. We see that the presence of about 1 part of HCl in 30,000 parts of water can be easily detected by the inversion test. At this dilution Günzburg's test gives only the very faintest result, the di-methyl-amido-azo-benzol test being, however, fairly distinct.

The HCl combined with proteid has no inversive action. As a quantitative test it is also very reliable as the following experiments show. Five small flasks were taken and there were put into (*a*) 10 cubic centimetres of cane sugar + 5 cubic centimetres of gastric juice and made up to 21 cubic centimetres by adding + 5 H_2O; (*b*) 10 cubic centimetres of cane sugar +

---

[6] Thus 20 cubic centimetres $\frac{N}{100}$ HCl required for neutralisation 16 8 cubic centimet [illegible] NaOH. When an ordinary filter paper (of 11 [illegible] placed in the 20 cubic centimetres of acid, [illegible] of alkali were necessary.

[7] Thus even in the cold we have found that the purest charcoal obtainable—viz., that prepared from cane sugar—is capable of taking up over 70 per cent. of the free acid and that this acid cannot be removed from the charcoal even by boiling with water. The only way by which it could be displaced was by placing the charcoal in a wide combustion tube and passing superheated steam over it, this latter being then condensed in a condenser.

[8] By using strong cane-sugar solutions the value of x for the same strength of acid is greater than when weaker solutions are employed and the experimental error is correspondingly less.

[9] Another advantage of employing this temperatures is that practically no evaporation takes place. If higher temperature be employed it is necessary to make the solution up to the original volume before examining it at this stage.

[10] That is after incubation for one night at 37° C.

cubic centimetres of gastric juice + 6 cubic centimetres $\frac{N}{100}$ HCl, representing 0·00219 gr. HCl = 21 cubic centimetres; (c) 10 cubic centimetres of cane sugar + 5 cubic centimetres of gastric juice + crystal of sodium acetate + 6 cubic centimetres H_2O; (d) 10 cubic centimetres of cane sugar + 8 cubic centimetres $\frac{N}{100}$HCl, representing 0 00292 gr. HCl, + 3 cubic centimetres H_2O; and (e) 10 cubic centimetres of gastric juice + 11 cubic centimetres H_2O and a small quantity of $\frac{N}{100}$ HCl added (this latter flask was used in order to correct for maltose if necessary). In flask (a) the amount of free HCl as calculated by the formula is 0·00259 gr.; this amount represents the quantity in five cubic centimetres of gastric juice (the amount used in the experiment); therefore, one cubic centimetre of gastric juice will contain 0·000518 gr. HCl, the percentage being 0·0518. In flask (b) the amount of HCl was found to be 0·004655 gr.; this consists of the HCl in gastric juice, plus a known quantity which had been added—viz., 0·00219 gr. Therefore, the amount of acid in the five cubic centimetres of gastric juice is equivalent to 0·004655 —0·00219 = 0·002465 gr. Therefore, one cubic centimetre of gastric juice contains 0·000493 gr. of HCl, giving a percentage of 0·0493 as against 0·0518, making a difference of 0·0025 per cent. of HCl in the vomit in the two flasks. In a second experiment the results are even better. In flask (a) the amount of HCl in one cubic centimetre of gastric juice was calculated to be 0·00055 gr., while in flask (b), which contained as before a known quantity of HCl as well as the unknown quantity in the gastric juice, the amount of HCl present in one cubic centimetre of gastric juice was 0·00054 gr., the difference being 0·001 per cent. in the two estimations. A third control was done with liquor pepticus (Benger). The percentage of HCl in this was found to be 0 2282. In flask (b) it was calculated to be 0·212, giving a difference of 0·016 per cent. in the two cases.

The percentage of free HCl in the gastric contents two hours after a mixed diet we have found to be, on an average, about 0·06. The following table gives the results of some determinations by the method detailed above:—

C. E. H.	*J. J. R. M.*
0 066	0 059
0·086	0 055
0·058	0·048
0·049	0·060

It will be seen that the percentage is a remarkably constant one, at least in the two cases investigated.

In conclusion we may state that the method is a comparatively simple one and that it can easily be carried out with one of the simple polariscopes used for the estimation of sugar in urine.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

LARGE PIECE OF GLASS IMBEDDED IN THE ORBIT FOR 20 YEARS WITHOUT CAUSING SYMPTOMS; REMOVAL.

BY J. HOGGAN EWART, M.D. EDIN.

ON July 4th, 1903, a married woman consulted me about a small sinus situated about two centimetres above the inner canthus of her left eye. She stated that 20 years ago a clock fell on her head the glass of which broke and made a deep cut across, and to the outer side of, her left eyebrow. This was sewn up and with the exception of a slight pricking about eight years ago which quickly passed off and a puckering of the skin over [illegible] lid there were no symptoms [illegible] when the skin broke and there [illegible] On examining this small opening (only half a centimetre in diameter) with a probe I found that a large triangular piece of glass was deeply *imbedded transversely above the eye,* the apex, lying on the nasal bones, being easily felt under the skin on the right side of the nose, and the base on the left orbital plate and tarsus. I removed it the next day.

[illegible] mained in this position for 20 years without causing symptoms or damaging the eyeball, upon which it might easily have encroached, the edges being quite sharp. It was much cracked. I was therefore glad that after a trial with a pair of forceps I removed it digitally or it would most certainly have splintered and caused great trouble. My thanks are due to Mr. M. G. Yunge-Bateman who kindly administered the anæsthetic.

Folkestone.

FRACTURED CLAVICLE WITH OSSIFIC UNION IN UTERO.

BY E. SYDNEY HAWTHORNE, F.R.C.S., L.R.C.P. IREL.

IN THE LANCET of May 9th last, p. 1310, you published under the heading "Looking Back" a case of the above extracted from one of your former issues dated May, 1825. As it may prove of interest to your readers I ask the courtesy of your pages to publish a case which has recently come under my observation.

On April 1st the patient, a married woman, was delivered of a full-term child without any trouble and on examining the infant I observed a small tumour of the size of a walnut situated at the centre of the right clavicle. This proved to be hard, dense, and immoveable and gave apparently no pain on pressure. No crepitus was felt on *moving the arm and shoulder blade and there was no* limitation of movement. The structures surrounding it were freely moveable and the skin over it was perfectly normal in appearance. I diagnosed a fractured clavicle united with callus surrounding the broken ends of the bone. I have frequently examined the infant during the past three months. The tumour has become less in size owing to absorption of the excessive callus and it is now represented by a small hillock on the upper surface with a corresponding depression beneath due to the ends of the bones being tilted upwards and in almost perfect apposition—a condition usually found in greenstick fractures of the young. There was no history of injury to the mother during her period of pregnancy.

Mudgee, New South Wales.

NOTE ON A CASE OF BERI-BERI.

BY DR. JULIO M. ESCOVAR,

ARMY MEDICAL SERVICE OF THE REPUBLIC OF COLOMBIA; GENERAL SURGEON TO THE PANAMA ARMY.

THE patient was a man, aged 32 years, who had been in Chiriqui Gaol since Sept. 14th and was admitted into Santo Tomas Hospital on Oct. 29th, 1902. There was no family history of importance. His general health had always been good except for several attacks of ague that had left an enlarged spleen. There was no history of syphilis, lead poisoning, or arsenical poisoning. He took but little alcohol. The urine was acid and free from sugar and albumin. The patient said that the trouble began on Sept. 28th with shortness of breath on exertion and a general sense of feebleness which was more accentuated in the legs. A week later he could not stand or walk and had lost tactile sensibility in the soles of the feet. He had full control of his rectum and *bladder; his appetite was poor; and his pulse was 90,* regular, and compressible. The heart sounds were energetic and accompanied with a soft diastolic murmur which was to be heard in the right second intercostal space and was audible also in the neck. The temperature ranged between 36·8° and 37·2° C. Thermic and tactile sensibility was lost from the tips of the toes up to the knees and the plantar and patellar reflexes were abolished but not the cremasteric. Having no suitable apparatus at hand the neuro-muscular reactions to electricity were not explored. Hypodermic injections of sulphate of strychnia daily were ordered, starting with two milligrammes and adding two milligrammes every day to the previous dose until 16 milligrammes were reached on Nov. 6th. The patient became worse slowly, diarrhœa came on, and he died from exhaustion on the 14th.

At the post-mortem examination, 24 hours after death, there was some general rigor mortis, the lips and cheeks were intensely blue, and there was drop-foot, especially on the left side. The abdomen contained some four ounces of straw-coloured fluid. There were many old fibrous adhesions between the parietal peritoneum and the spleen and the liver, the latter having the appearance found in those who die from mitral stenosis. The weight of the spleen, which was of hard consistence, was 420 grammes. The kidneys and the remainder of the abdominal contents were normal. Nothing abnormal was found in the lungs and pleural cavities. There were three ounces of serous fluid in the pericardial sac; there were no pericardial adhesions. The heart had four milky patches distributed on the external aspect of the ventricles; its weight was 412 grammes. The thickness of the walls of the left ventricle was 32 millimetres; there were many adherent old white clots in both ventricles; but the endocardium, orifices, and valves were healthy. An incision was made from the gluteal ridge to the calf in the median posterior line of the left thigh, exposing the great sciatic nerve; the subcutaneous fat was scanty, the muscles had the ordinary appearance, and there was no congestion, discolouration, or change appreciable to the naked eye either in the nerve or in its sheath. The head and spinal canal were not opened.

Herewith I inclose for microscopical examination a specimen taken with every aseptic precaution from the left sciatic nerve near its bifurcation in the popliteal space.

Panama.

⁂ The specimen in question was examined microscopically by a member of our staff but did not exhibit any pathognomonic change.—ED. L.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Prœmium.

EAST LONDON HOSPITAL FOR CHILDREN.

FIVE CASES OF PURULENT PNEUMOCOCCIC ARTHRITIS IN CHILDREN.

(Under the care of Mr. L. A. DUNN, Mr. H. BETHAM ROBINSON, and Dr. H. MORLEY FLETCHER.)

FOR the notes of the cases we are indebted to Mr. Leonard S. Dudgeon, late pathologist to the hospital (now superintendent of the clinical laboratory at St. Thomas's Hospital), and Dr. W. P. S. Branson, pathologist to the hospital.

CASE 1.—A girl, aged five months, was admitted under the care of Mr. L. A. Dunn on Jan. 31st, 1903. Two weeks before admission she had "bronchitis," from which she had nearly recovered when, on Jan. 27th, she had a fit, at which time it was first observed that the left knee was flexed, swollen, and painful. The child was well-nourished and free from organic disease apart from the affection of the knee. The latter was swollen, red, hot, shiny, and freely fluctuating. The general condition was good, the fever was only moderate (from 100° to 102° F.), and the general appearance was not that of grave illness. The joint was opened by lateral incisions and a quantity of pus was evacuated. With the operation the fever fell and for five days the child seemed to be mending. Then followed a recurrence of the fever with marked cervical rigidity, on the strength of which the right tympanic membrane, which appeared to be inflamed, was punctured, but without discharge of pus or relief from the symptoms, and two days of persistent vomiting ended in death on the fourteenth day from the commencement of the illness.

Necropsy.—The post-mortem examination was made on Feb. 14th. The body was somewhat wasted; the left knee-joint was well drained, containing only a small quantity of thick reddish-yellow odourless pus, and there was no local disease of bone or bone marrow appreciable by the naked eye. There was no other evidence of disease except for a small quantity of thick yellow pus in the right middle ear.

Bacteriological examination.—At the operation upon the knee cultures were made from the pus upon various media and resulted in the growth of a delicate organism conforming in all cultural characteristics and morphology to the pneumococcus of Fraenkel. At the necropsy a culture was taken in a sterile glass syringe from the blood in the right ventricle and resulted in the growth of an organism in all respects identical with that found during life in the pus from the affected joint. Unfortunately no culture was made from the pus found in the middle ear.

CASE 2.—A boy, aged six years, was admitted under the care of Mr. H. Betham Robinson on March 23rd, 1903. The patient had been ill for three weeks with earache and subsequent otorrhœa, when on March 17th he complained of pain and swelling in the left knee-joint, followed on the next day by similar affections of the right hip and wrist. There was no history of rigor, convulsion, or any other symptom of note. The patient on admission appeared to be very ill and lay curled up in bed with all his joints flexed. He had a troublesome dry cough and was slightly delirious, though his fever was moderate. Nothing abnormal was to be discovered in the lungs or heart. The left knee-joint was in all respects similar to that of the patient in Case 1—swollen, red, hot, shiny, and fluctuating—while the right hip and wrist appeared to be in a less advanced state of inflammation, and this in the latter seemed not to involve the joint but to lie superficial to it. The urine was normal. The knee-joint was opened and a quantity of thin pus and flakes of fibrin were evacuated and a similar result attended the opening of the hip-joint. The swelling over the wrist was incised without result. Little benefit resulted from the operation, though the wounds progressed favourably. Fever continued high at night with morning remissions and with gradual loss of strength, but without specific complications; the child died from asthenia 20 days after the operation. No post-mortem examination was allowed. Pure cultures of the pneumococcus were obtained from the pus found in the joints.

CASE 3.—An infant, aged six months, was admitted under the care of Dr. H. Morley Fletcher on April 10th, 1903, with a history of tenderness and swelling of the right leg for eight days. On admission the child was found to be well nourished but acutely ill. The temperature was 103° F. The contents of the chest seemed to be normal and signs of disease were confined to the right leg which was diffusely swollen from the hip downward, semi-flexed at the knee, and very tender. Four days later the patient was much worse, the temperature was seldom below 102°, the right leg was more swollen, and fluctuation was to be obtained above the patella. In addition there was a small abscess over the proximal interphalangeal joint of the third finger of the right hand. Lateral incisions into the knee-joint set free a small quantity of deeply blood-stained pus, while yellow pus was obtained from the phalangeal arthritis. There was no relief from the operation and the patient died within 12 hours. No post-mortem examination could be obtained.

Bacteriological examination.—Films prepared from the pus in the joints and stained with the ordinary aniline dyes showed cocci, diplococci, and streptococci, while cultures yielded a pure growth of the pneumococcus.

CASE 4.—A boy, aged 14 months, was admitted under the care of Mr. Betham Robinson on April 21st, 1903. Three weeks before admission the patient underwent an attack which was pronounced to be pneumonia, since which he had been losing flesh without definite symptoms until one week before admission when the right elbow was observed to be swollen and tender. The child was pale and thin and suffered from slight fever. The right elbow-joint was swollen, red, very tender, and fluctuating, and there was some swelling in the anterior triangle of the neck on the left side; otherwise, as in the other cases, there was no sign of organic disease. The elbow-joint was opened on the day of admission and about an ounce of pale yellow, odourless pus was evacuated. On the next day, as there was difficulty in swallowing, the swelling in the neck was incised from the outside and a small quantity of thick yellow pus escaped. The patient improved, but on May 7th the right knee-joint was noticed to be swollen and fluctuating. Exploration with a needle yielded a negative result, but on incision of the joint about an ounce of clear fluid was evacuated and the joint cavity was found to be lined by a gelatinous false membrane which was easily separable by the finger. The patient now made an uninterrupted recovery and was sent to the convalescent home on June 4th

Bacteriological examination —It will be noticed that there were three separate incisions, each yielding a fluid of different character, moderately thick pus from the elbow, pus still thicker from the neck, and from the knee a clear fluid and a fibrinous membrane Culture tubes were inoculated with pus from the elbow and yielded on all the media employed a small growth in 24 hours One cubic centimetre of a 24 hour broth culture injected into the peritoneal cavity of a white mouse led to its death within 18 hours and films prepared from the heart's blood, spleen, and kidneys showed numbers of cocci, diplococci, and short chains in every specimen A pure culture of the pneumococcus was also obtained from the heart's blood and the spleen A coccus was cultivated from the abscess in the neck which in morphology and cultural characteristics resembled the staphylococcus albus, but it is to be regretted that a careful investigation of this organism was not undertaken No organisms could be seen in the film preparations from the membrane lining the knee joint and all cultures were sterile

CASE 5 —An infant, aged one year and nine months was admitted under the care of Mr Dunn on May 28th, 1903 Five weeks before admission the patient had measles, three weeks later flexion of the right hip joint was observed with tenderness on movement The patient was an ill-nourished and weakly child. The right hip joint was flexed and surrounded on all sides by a large fluctuating swelling to which an impulse was transmitted on coughing The temperature was found to be 100°F Elsewhere there was no sign of disease On incising the abscess a large quantity of greenish yellow odourless pus was evacuated from a cavity extending widely in all directions, notably downwards where it crossed the ischium and entered the ischio rectal fossa The hip-joint was disorganised and the head of the femur was dislocated upon the dorsum ilii.[1] In spite of the extent of the lesion the temperature fell after the operation and the child rapidly improved. On bacteriological examination the pus from the hip joint yielded a pure culture of the pneumococcus

Remarks by Mr DUDGEON and Dr BRANSON —The cases above recorded offer several points of interest In the first place they are, with one exception, cases of purulent arthritis in *infants*—in itself an uncommon condition, moreover, they stand out in sharp contrast with such cases as are due to the staphylococcus aureus, streptococcus, &c It has been our experience, and that of our predecessors that the pneumococcus practically monopolises the etiology of infective arthritis during infancy and about up to the end of the first hemi decade and the type of the disease is peculiar Except in the severest cases the constitutional symptoms do not keep pace with the extent of the local lesion and a baby whose knee joint is distended with pus may sleep and eat well, a condition inconceivable in the case of staphylococcal or streptococcal infections of so large a joint The fever is usually irregular and moderate, while the appetite survives and prevents extreme emaciation

The character of th[illegible] almost distinctive, t[illegible] complete absence of [illegible] pain, tenderness, and distension of the joint all point to an acute inflammatory process In none of the above cases was there any brawny swelling or œdema worth mentioning The disease is accompanied in most cases by an intense pallor which is best compared to that occurring in long-standing cases of empyema in children, which condition, it will be remembered, is almost invariably pneumococcal in origin

The variations in the character of the pus from such joints as these are of interest and probably of prognostic value In cases of moderate severity it is fairly thick, yellow, but with a distinct shade of green, odourless, and very prone to fibrin-formation and deposit of lymph, similar in fact, in every way to the common type of pus from the empyemata in children On either side of this type there occur varieties which appear to measure the intensity of the process at work Thus in Case 3 the pus was deeply blood stained, in Case 2 it was thin and to the naked eye resembled turbid serum, though microscopically loaded with pus cells The patients in both of these cases died, thereby confirming our belief in the ominous import of thin pus in pneu[illegible] commonly results On the other side of the type may be placed such conditions as that present in the knee joint of Case 4 where a gelatinous membrane, consisting of fibrin and pus cells, inclosed a clear fluid Whatever the antecedents of this condition it was at all events very chronic and comparatively harmless

The prognosis, if based upon these meagre statistics, would seem to be very grave, for three patients out of the five died No doubt the average mortality is not so high Herrick, however, obtained a mortality of 65 per cent. in the 52 cases which he collected from the literature. One patient of the five had been ill for a week with swollen joints before admission and it is reasonable to believe that his chances were prejudiced by this long delay But with all allowances it cannot be said that our experience tallies with that of those who consider the prognosis in cases of pneumococcal arthritis to be favourable

Treatment was carried out on accepted principles and the affected joints were drained from side to side It was generally found possible to remove the drainage tube on the third day, after which the discharge gradually abated Even in the worst cases the treatment of the local condition was fairly satisfactory and free from complication. In the one case where the patient had been discharged cured the mobility of the elbow joint, from which thick pus was obtained, was considerably diminished, the knee joint which contained the clear fluid and membrane above described, has escaped abnormal limitation of movement.

Bacteriology —In all these cases a complete bacteriological examination was made and in one case additional confirmation was gained by animal inoculation The organism stained by Gram's method and with the various aniline dyes A growth was obtained on a variety of media—viz, agar, bouillon, blood agar, glycerine agar, and blood serum In those cases in which it was tried no growth was obtained on gelatin (melting point about 24°C) We regret that the medium advised by His for the differentiation of the pneumococcus from the streptococcus was not employed The organism was found to be capsulated in the pus obtained from the infected joints and in two cases from the blood agar tubes The serum reaction was not attempted for the diagnosis of any of these cases

Pathology —It is a curious fact that there was no case of inflammation of any of the serous sacs or important viscera in any of our patients, although pneumococcal inflammation was proceeding actively in certain joint cavities, and when we consider how important a part the pneumococcus plays in the acute diseases of children the freedom of these five cases from all the common lesions of this organism must be admitted to be remarkable. There is, however, this to be remembered, that three of these five patients died, one of whom yielded the pneumococcus in pure culture from the heart's blood at the necropsy It is fair to say, therefore, that this child died from pneumococcic septicæmia The other two fatal cases lacked a post-mortem investigation, but we personally believe that the pneumococcus might have been cultivated from the heart blood in these cases also and that death occurred in them, as in the other, from septicæmia, in which event the absence of organic disease in the viscera is more intelligible.

The above belief is based upon investigations into the real cause of death in cases where necropsy reveals no more, perhaps, than an infinitesimal area of broncho pneumonia In a dozen cases of this kind the pneumococcus was obtained from the heart's blood, generally in pure culture, and similar results attended the examination of other varieties of pneumococcic infection—e g, lobar pneumonia, severe broncho pneumonia, meningitis, empyema, &c Even in patients dying with other lesions in themselves fatal, such as generalised tuberculosis, we have cultivated this organism from the heart's blood and are compelled to come to the conclusion that the pneumococcus plays an even more important part in the acute infections of children than is usually said and that a generalised infection of the blood by this organism is a fairly common event Whether this septicæmic condition attends fatal cases only is a question that awaits further investigations into the bacteriology of the blood during life

As regards the primary focus of infection, it will be recalled that one patient had suffered from an attack of "bronchitis" previously to the joint affection, a second an attack of otorrhœa, and a third one of "pneumonia." Assuming that these diagnoses were correct we have a possibly exciting cause for three out of the five cases. Netter, quoted by Muir and Ritchie, states that out of 46 cases of pneumococcic infection of children, otitis media was the primary lesion in 29, broncho-pneumonia in 12, meningitis in two, pneumonia in one, pericarditis in one, and pleurisy in one. No case of primary arthritis enters his list.

---

[1] [illegible] t appears to be most common in [illegible] so described by Fernet and Lorraine [illegible] is completely destroyed the surround[illegible] were disintegrated and marked with streaks of pus while the articular cartilages were disorganised only rough denuded bone remaining

The important and variable part played by the pneumococcus in children can be well illustrated by the following facts. During the last six months 15 cases of pleuritic effusion have supplied fluid for bacteriological examination at the East London Hospital. In 11 the pneumococcus was isolated in pure culture, in two the culture was sterile, and two gave a growth of staphylococcus albus. The pneumococcus was also obtained during that period from two cases of suppurative pericarditis, four cases of meningitis, and two of peritonitis. In many of these cases it is impossible to be certain of the primary lesion but probability inclines to the middle ear.

Cave, in an excellent monograph on this subject, found in a total of 31 cases an antecedent pneumonia as the cause in 28, a result widely differing from our own; but his cases were almost entirely confined to adults, while ours were all in young children. In two cases quoted by him in which the disease affected children a pneumonia followed the arthritis.

There was no suggestion of trauma in the cases under notice, a fact that eliminates a possible explanation, for it has long been known that injury to a joint, followed by inoculation elsewhere with the staphylococcus aureus, will in animals determine a suppurative arthritis of the injured joint. The same thing is true of the pneumococcus; indeed, arthritis has been produced by section of the sciatic nerve and subsequent inoculation with the pneumococcus, the inflammation affecting the joints of the injured limb. Cave found direct evidence of previous damage to the affected joint in ten of his 31 cases, but no doubt the greater age of the patients in his series increased their liability to injuries of the joint by comparison with the youthful subjects of this paper.

Our best thanks are due to Mr. Dunn, Dr. Morley Fletcher, and Mr. Betham Robinson for permission to make use of the above cases.

Reviews and Notices of Books.

Tropical Diseases: A Manual of the Diseases of Warm Climates. By Sir PATRICK MANSON, K.C.M.G., M.D., LL.D. Aberd. 8vo, pp. 756. With 130 Illustrations and two Coloured Plates. New and revised edition. London: Cassell and Co., Limited. 1903. Price 10*s.* 6*d.*

SINCE the first edition of this work appeared in 1898 several reprints and two new editions have followed in quick succession. The necessity for these frequent issues is owing to the popularity of Sir Patrick Manson's book and to the rapid changes which have taken place during the past five years in tropical pathology. The text is arranged under seven sections apportioned into 45 chapters.

Section I. deals with Fevers, among which malaria occupies the most prominent place. There are several noticeable changes in this part of the work. The term "plasmodium" is definitely set aside as being a scientifically inaccurate nomenclature for the malaria hæmamœba; the anatomy of the mosquito is more minutely described and illustrated; the methods of staining malarial blood have been improved of late although they are all modifications of the original Romanowsky's method; and the hæmocytozoa of animals according to Laveran's grouping are shortly considered. The most noticeable feature in this section is the general tone of confidence adopted concerning the mosquito theory of malaria which, but a few years ago, was put forward in the first edition of this book as an unproved suggestion. The theory so well enunciated by Sir Patrick Manson in 1894 has now passed from mere conjecture and has become an accomplished fact. Under Section I. is included Trypanosomiasis, which as a disease affecting man has only been definitely known since September, 1902, when Forde published his case of anomalous fever, mentioning that he had found a parasite in the blood which was recognised by Everett Dutton as a trypanosoma. Spotted fever, a disease met with in the districts of Montana and Idaho, U.S.A., is also included amongst the fevers for the first time. In Chapter XX. are discussed "unclassed fevers of the tropics"; their number and variety offer a fruitful field for investigation and no doubt in the near future several of these ill-understood diseases will be further studied and classified.

Section II. is devoted to Beri-beri, Epidemic Dropsy, and Sleeping Sickness, these ailments being grouped together under the title of "General Diseases of Undetermined Nature." The last named has, within the past 12 months, assumed an absorbing interest, for sleeping sickness has spread beyond the Congo Basin, where it was originally met with, and reached Central Africa and even threatens the inhabitants of the Nile Valley. Originally considered to be associated with the presence of filaria perstans in the blood, an assumption now practically set aside, its etiology was subsequently referred to the presence of a certain diplococcus; but showing how rapidly facts accumulate in this sphere of inquiry, even since the appearance of this manual evidence of a confirmatory character has been obtained, through the investigations of Castellani and Bruce, that the disease is associated with, or caused by, a trypanosome met with in the cerebro-spinal fluid.

Of the remaining sections No. III. is devoted to Abdominal Diseases, No. IV. to Infective Granulomatous Disease, No. V. to Animal Parasites, No. VI. to Diseases of the Skin, and No. VII. to Local Diseases of Uncertain Nature.

Perhaps the most complete and important piece of new work related is the discovery of the relationship of the mosquito to yellow fever. The United States Army Commission investigated the mosquito theory of yellow fever in a wholly convincing manner, with the result that not only the means by which yellow fever is carried has been settled, but, as has been proved in Havana, the extermination of the stegomyia mosquitoes has resulted in the disappearance of the disease from that city. The possibility of the introduction of yellow fever into Asia by way of the Central American Canal is referred to and the means of its prevention are described. Another theory which now becomes a scientific fact is that the filarial embryo finds its way into the proboscis of the mosquito, almost conclusively proving what was long ago conjectured by Sir Patrick Manson that the parasite is conveyed to warm-blooded animals whilst it feeds upon them. Many other new facts deserve notice, but the above will suffice to show the necessity for a new edition of "Tropical Diseases." Tropical pathology is advancing so rapidly that from week to week, certainly from month to month, new conclusions are arrived at and fresh information is brought to light. It will be seen from our review of the report of Dr. Lacerda's researches and from the letter from our New York Correspondent which appears at p. 345 that the theory that the mosquito is the only means of transmitting yellow fever is not universally accepted, though without doubt it is the most important agent.

Throughout every page of the book we recognise the handiwork of a master of his subject. No disease is touched upon that does not afford proof that it has been carefully considered and the chaff separated from the wheat. Not only are we indebted to Sir Patrick Manson for much that is new in the book but the work of others is duly recognised and appreciated, the whole forming a compendium of tropical diseases of pre-eminent excellence. The plates and illustrations are good and of a serviceable character. The practitioner in the tropics will welcome the new edition of this manual, a book which he recognises as essential for him to have and one on the general accuracy of which he can thoroughly rely.

Recherches sur la Cause et la Prophylaxie de la Fièvre Jaune, faites au Laboratoire de Biologie du Musée National de Rio de Janeiro. (Researches upon the Cause and Prophylaxis of Yellow Fever, made at the Biological Laboratory, National Museum, Rio de Janeiro.) By Dr. J. B. LACERDA. Rio de Janeiro: Imprenza Naiconal. 1902. Pp. 68 + 11 Plates.

THIS work by Dr. Lacerda is divided into two parts—viz., the first, in which are detailed the observations and experiments demonstrating the cause of yellow fever to be a *ferment;* and the second, containing an account of the different means of access of the disease to the pathogenic germ. Dr. Lacerda remarks that although so much has been done, especially by Sanarelli, to elucidate the cause and pathogeny of this malady, yet that there are a number of facts not yet explained. He holds that this disease as regards its causation differs from the type common to the infectious diseases in general and that it has a distinct individuality so as to merit a special location amongst the zymotic affections. From his researches he deduces the following facts: that the cause of yellow fever is a ferment present in the blood, the vomit, the liver, the stomach, and the kidneys of the patient, the liver being the organ more especially affected; that this ferment reproduces itself in the digestive canal of the culex, where it is found to possess the same attributes as it has in the blood and organs of those attacked with the disease; that the ferment is acid and that consequently the most rational treatment is by alkalies. The success of this treatment, first proposed by Sternberg, was shown, amongst others, by Guardia and Martinez at Havana, where the mortality following it was only 13·59 per cent. as compared with a mortality of 43·5 per cent in cases not so treated.

Regarding the means of entrance into the human organism the author holds that the poisonous agent is infective either by subcutaneous inoculation or through the stomach. The stings of the culex that has fed on a yellow fever patient are chiefly the agency by which the disease is spread in the former case. But Dr. Lacerda does not consider this to be the sole method of the spread of the disease, for he has caused rabbits to succumb with the symptoms and post-mortem lesions of yellow fever after introducing into their gastric cavity the cultivated ferment of the disease. How the pathogenic entity reaches the stomach is not definitely determined; it is certainly not by the drinking water, for according to Dr. Lacerda not a single valid fact can be brought forward in its favour in this respect. He considers that flies, after settling on the excreta of yellow fever patients, alight on articles of food and so infect them. One of his arguments against the culex being the sole agent in the transmission of the disease is this. The normal life of the mosquito does not exceed two months. How, then, according to this theory, can yellow fever, after being absent for six months in Rio de Janeiro, reappear at the end of this period? Again, in Louisiana in 1850 an epidemic of yellow fever was not modified by a temperature sufficiently low to produce ice, yet the mosquitoes there were all quiescent during this period of low temperature.

Dr. Lacerda concludes his work with the description of the preparation of his "vaccine" and announces his belief that by means of its repeated inoculation strangers newly arrived in Brazil will be rendered immune for six months against an attack of yellow fever and will acquire an absolute immunity after a sojourn of two or three years in the yellow fever zone, provided that they are reinoculated each year during the epidemic season. The "vaccine" is prepared from the toxic materials in the liver of rabbits which have succumbed to the infection of the "hyaline cellules," the name given by Dr. Lacerda to the ferment of yellow fever. At the same time protection against the bite of the mosquito must be carried out.

Traitement de l'Avortement. (The Treatment of Abortion.) By Dr. MOISE MISRACHI. With a preface by Dr. J. A. DOLERIS. Second edition. Paris: R. de Rudeval. 1902. Pp. 366. Price 6 francs.

THIS book, of which a first edition appeared in 1894, has been written by the author mainly with a view to show the advantages to be derived from the treatment of cases of complicated or incomplete abortion by early curettage. The principle of such early intervention is confirmed by Professor Doléris who contributes an introduction. The frequency with which the author has had occasion to interfere will be seen from the fact that in a total of 248 cases of abortion he has found it necessary to empty the uterus no less than 187 times—viz., in 75·4 per cent. of his cases. As he points out, however, practising as he does in a country district amongst ignorant people, he is often only called in when some complication is present. In only 120 cases has he seen the patients from the very commencement and been able to carry out the whole treatment of the case. Of these 120 cases, in 59 he has been obliged to interfere, or in 49·1 per cent. In two cases the patient was suffering from septicæmia, while in 39 cases the indication for interference was hæmorrhage. All the 59 patients recovered. The results are certainly very good, but it must be remembered that many cases in this plan of treatment are operated upon which under ordinary conditions would be left alone and would no doubt do quite well. The book contains a large number of illustrative cases and the subject is discussed very fully although perhaps hardly in a very convincing manner. We are not in agreement with the author in his fervid recommendation of the curette, and while we quite admit that when the proper indications are present the uterus should be emptied, yet we would much prefer the finger for this purpose to the curette, and it would require a great deal more evidence than Dr. Misrachi has brought forward to convert us to the contrary opinion. Under the treatment of inevitable abortion the writer recommends very strongly the use of antipyrin and of viburnum prunifolium as uterine sedatives. The work is interesting but discursive, presenting only one view of a very important question.

Eye Symptoms as Aids in Diagnosis. BY EDWARD MAGENNIS, M.D. R U.I., D.P.H. R C.S. Irel., late Clinical Assistant at the Royal London Ophthalmic Hospital. London: Simpkin, Marshall and Co., Limited. Bristol: John Wright and Co. 1903. 12mo, pp. 103. Price 2s. net

ALTHOUGH Dr. Magennis has evidently taken much pains with this little book we doubt whether the class of men for whom it is written will derive much advantage from its perusal, for if they can see the details of the fundus of the eye that are here described, such, for example, as obliteration of the outline of the papilla, radiating striæ fading off gradually into the surrounding tissue, swollen and tortuous veins, and small hæmorrhages and exudations in the neighbourhood of the disc, they must have been dull and incurious indeed if they had never inquired what diseases these conditions connoted. It is almost an unavoidable defect of booklets like this that with great condensation obscurity creeps in. Thus all that is included under Lagophthalmus is that it is synonymous with "hare's eye," that it is an inability to close the eyelids, and that "it is present in Basedow's or Graves's disease, where it is often so aggravated as to cause blindness"; how or why is not given. The author remarks that the cornea, the lens, and the vitreous are of no diagnostic value, a sweeping statement that is open to discussion and we think to refutation. In commenting on the treatment of iritis Dr. Magennis mentions atropine, lead, leeches, protection of the eyes from light, and constitutional treatment. We should have omitted the lead and should have mentioned opium. The relation of the pupil reflex to lesions of the nervous system is well given; a woodcut showing the course of the nerve fibres might have been advantageously introduced. A few errors have crept into the letterpress. "Punctum lacrymalis" should be "punctum lacrymale," an error that occurs in the text and is repeated in the index. "Purkinge" should be "Purkinje" or "Purkinye." The book might be increased in size with advantage.

LIBRARY TABLE.

Flora of Thanet: A Catalogue of the Plants Indigenous to the Island, with a Few Rare Aliens. By G. M. PITTOCK, M.B. Lond., and Friends. Margate: R. Robinson and Co. Pp. 14. 1903.—We have received from Dr. Pittock his catalogue of the Flora of Thanet, founded upon the "Flora Thanetensis" published by Mr. John Flower some 50 years ago. Mr. Flower's list numbered 454 plants and included the algæ. The present list of 565 plants is exclusive of the algæ. Every plant recorded in Mr. Flower's work has been verified by Dr. Pittock and his fellow workers or has been rejected as not now to be found, so that their revised list, if not exhaustive, may be considered as nearly so. The catalogue is a simple list of the classical names of the flowers, notes of the localities where they were discovered having been prudently omitted lest ruthless collectors should descend upon the rare varieties and exterminate them, as is their disgusting wont. The life of the medical man in the country is nowadays so onerous and so ill-paid that few general practitioners have leisure to turn aside and to seek diversion from the daily routine by excursions into some scientific pursuit. This is to be regretted, for medical men are by their accurate training fitted to examine and to report upon the flora and fauna of the localities in which they reside. Systematic collation of local work done by members of our profession would have inestimable scientific and historic value, and we wish that we could chronicle more efforts on the part of medical men in the direction of field natural history.

Practical Handbook of the Diseases of the Eye. By D. CHALMERS WATSON, M.B., F.R.C.P. Edin., Ophthalmic Physician, Marshall-street Dispensary, Edinburgh. Second edition, with nine Coloured Plates and 31 Illustrations in the text. Edinburgh and London: William Green and Sons. 1903. Small 8vo, pp. 276.—This small book is one of those of which so many have recently appeared intended for students who are attending eye wards as clerks or dressers and for practitioners who have not had the opportunity of studying ophthalmology in their hospital career and who desire to acquire some information upon that subject. Such works are useful in familiarising the reader with the names and the more prominent features of the chief forms of disease of the eye, the names of the principal drugs in common use, and some of the indications for their administration. The division of the text into short paragraphs with separate headings may possibly assist some learners, but it has the disadvantage of rendering the description of any disease such as iritis exceedingly uninteresting, reducing it, in fact, to a mere syllabus. The woodcuts in the text are well executed, but the chromo-lithographs, though recognisable as representations of certain conditions, admit of considerable improvement.

JOURNALS AND MAGAZINES.

Caledonian Medical Journal.—The July number contains an account of the twenty-third annual meeting of the Caledonian Medical Society, held at King's College, London, on July 11th. The society now consists of 214 ordinary and 14 honorary members; at this meeting a lady member was for the first time elected. Three of the essays sent in competition for the Stewart Celtic prize on "Old Highland Therapy" were so nearly equal in merit that £5 were added to Dr. Stewart's donation of £10 and the prize was divided between these three competitors. Their names are Mrs. K. Whyte Grant, New Zealand; Mrs. Robert Moodie, Edinburgh; and Mr. Henry Whyte, Glasgow. The essays will be published in the next three numbers of the journal. At the annual dinner, which was held on July 10th at the Trocadéro Restaurant, the toast of "Caledonia" was proposed by the Bishop of Exeter and Highland airs were played by the boy-pipers of the Royal Caledonian Asylum. The last part of the proceedings was a river excursion to Windsor and Eton. The presidential address, delivered at the meeting by Dr. H. Cameron Gillies of London, is printed in the journal under the heading of "The Caledonian Idea." It is mainly an interesting historical inquiry into the etymology of the word Caledonia which, he says, first occurs in the writings of Lucan about A.D. 63; the displacement of the original inhabitants by the "Scottish invasion" from Ireland is also discussed.

Dublin Journal of Medical Science.—The original articles in the July number are:—On two cases of Lymphatism, by Dr. George Peacocke; on the Late Cholera Epidemic in Egypt, by Lieutenant-Colonel G. F. A. Smythe, R.A.M.C.; and Notes on a Year's Asylum Work, by Dr. W. R. Dawson.

Mercy and Truth.—The principal article in the July number is a description of a visit to Dera Ismail Khan in the North-west of India by Mr. Arthur Neve, F.R.C.S. Edin.

THE LANCET LABORATORY.

"TABLOID" QUININE SALICYLATE.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, LONDON, E.C.)

WE have previously had occasion to examine tabloids of quinine salicylate containing three grains of the salt. We have since received specimens containing one grain of quinine salicylate which enables smaller doses to be given at more frequent intervals. The drug has been employed in influenza, neuralgia, and diarrhœa. The salicylic acid from which the salt is prepared is stated to be physiologically pure.

STRONG BEEF TEA.

(GEORGE MASON AND CO., LIMITED, WALHAM GREEN, LONDON, S.W.)

This "strong beef tea" is contained in tins of a capacity of one and a half pints. It is a "whole" beef "tea," since it contains not only the extractives of the meat but the muscular fibre also in a finely comminuted state. According to our analysis the amount of meat fibre is 3·74 per cent. or equal to one ounce of dried fibre in one and a half pints. The extractives and albuminous matters in solution amounted to 12·95 per cent., of which 2·37 per cent. is due to mineral salts. The "tea" has a pleasant flavour of beef and is very well suited, as is claimed, "for emergency or general use at nursing institutions" It is both appetising and nourishing and its concentrated condition is an advantage

MALTOVA

(MALTOVA LIMITED, 11, NEW STATION STREET, LEEDS)

We have already expressed a favourable opinion in regard to this preparation which consists of a combination of an active malt extract with raw egg Maltova has recently been improved in an important dietetic direction by enriching it with those lime salts which are necessary for the mineral nutrition of the body Moreover, maltova is now contained in a wide mouthed bottle which is straight in shape and is provided with a screw cap In this way the removal of the sticky contents may be effected in a cleaner and more convenient manner than before Judging from the amounts respectively of fat and proteid which we obtained on analysis the proportion of egg is not very high, the sugar amounting to at least, and probably more than, 70 0 per cent

(1) CHELTINE NUTRIENT MILK CHOCOLATE AND (2) CHELTINE MALTED MILK CHOCOLATE

(CHELTINE FOODS LIMITED CHELTINE WORKS CHELTENHAM)

(1) To the nutrient milk chocolate, which is excellent as regards flavour, a proportion of soluble proteid of milk has been added and accordingly our analysis shows a high percentage of nitrogen The complete analysis was as follows moisture, 0 15 per cent, mineral matter, 0 16 per cent, fat, 27 72 per cent, proteid, 29 98 per cent, and sugar and other cocoa constituents, 41 99 per cent The chocolate is an economical and nutritious sweetmeat (2) The malted chocolate milk contains, in addition to full cream milk and cocoa extract, a proportion of cheltine soluble maltose food[1] Our analysis gave the following results moisture, 0 24 per cent, mineral matter, 0 26 per cent, fat, 35 52 per cent, proteid, 12 50 per cent, and maltose and cocoa extractives, 51 48 per cent The proportion of moisture is again very low The preparation has an agreeable malty flavour and is a very palatable nutrient compound.

COGNAC BRANDY (THREE STAR)

(HENNESSY AND CO AGENCY: TWISS AND BROWNINGS 47 MARK LANE, LONDON, E.C)

The analysis of this brandy gives results entirely in agreement with those yielded by genuine grape spirit distilled and matured in the celebrated Cognac district The figures were as follows alcohol, by weight 40 80 per cent, by volume 48 21 per cent, equal to proof spirit 84 49 per cent, extractives, 0 70 per cent containing sugar, 0 20 per cent In regard to secondary products the following were the results, given in grammes per hectolitre of absolute alcohol present acidity reckoned as acetic acid, 74 52, aldehydes, 16 56, furfural, 1 65, ethers reckoned as ethyl acetate, 109 29, and higher alcohols, 124 20 The relation of these constituents to each other is exactly that which is found in genuine brandy Thus the ethers occur in very nearly the same amount as do the higher alcohols, while the furfural is less than half of that which is commonly found in pot still whisky The brandy is very satisfactory to the palate, it is smooth and soft, possessing that peculiar *finesse* characteristic of the brandy from the celebrated district of Cognac For medicinal purposes it is important to employ a spirit of this undoubtedly genuine type.

GRANDE CHAMPAGNE (GRANDE IDEAL)

(LOUIS BULTEAUX PERE, EPERNAY LONDON AGENCY 29, LUDGATE HILL, E.C)

We have examined samples of the 1893 and 1895 vintages of this brand As will be seen, there are differences of composition between the two wines which are of dietetic importance The analysis of the 1893 wine was as follows alcohol, by weight 11 23 per cent, by volume 13 90 per cent., equal to proof spirit 24 36 per cent., extractives, 2 75 per cent, mineral matter, 0 07 per cent, volatile acid calculated as acetic acid, 0 072 per cent., fixed acid calculated as tartaric acid, 0 39 per cent., sugar, 1 34 per cent., volatile ethers calculated as ethyl acetate, 0 202 gramme per litre, and fixed ethers calculated as ethyl tartrate, 0 45 gramme per litre The wine is described as "brut," a description which is quite in accordance with the small amount of sugar shown in the above analysis The wine has excellent bouquet and taste and the samples which we examined were in fine, sound condition The analysis of the 1895 wine was as follows alcohol, by weight 11 69 per cent, by volume 14 46 per cent, equal to proof spirit 25 34 per cent., volatile acidity reckoned as acetic acid, 0 12 per cent, fixed acidity reckoned as tartaric acid, 0 45 per cent., extractives 1 69 per cent, mineral matter, 0 10 per cent, sugar, 0 21 per cent, volatile ethers reckoned as ethyl acetate 0 343 gramme per litre, and fixed ethers reckoned as ethyl tartrate, 0 968 gramme per litre This wine is also described as "brut and, as will be seen from the analysis, it is for all practical purposes free from sugar On this account it is suitable for those who must avoid an excess of sugar The wine is quite dry to the taste, the flavour is delicate, but in this regard shows less 'character' than does the previous specimen

(1) IMPERIAL WHISKY AND (2) O V H WHISKY

(W GREER AND CO, LIMITED GLASGOW)

(1) The Imperial whisky gave the following results on analysis extractives, 0 110 per cent, and alcohol, by weight 38 83 per cent., by volume 46 08 per cent., equal to proof spirit 80 75 per cent. In regard to secondary products the following were the results expressed in grammes per hectolitre of absolute alcohol present acidity reckoned as acetic acid, 39 06, aldehydes, 14 32, furfural, 3 49, ethers reckoned as ethyl acetate, 106 76, and higher alcohols, 108 50 These results indicate a blended malt spirit and accordingly the taste is delicately malty Further, the spirit has been thoroughly matured in sherry casks which probably accounts for the higher amount of ethers than is usual in whisky The spirit is evidently of good quality and is an excellent and palatable blend. (2) The O V H whisky gave the following results on analysis extractives, 0 12 per cent, and alcohol, by weight 39 55 per cent., by volume 46 86 per cent., equal to proof spirit 82 12 per cent. The secondary products were estimated to be as follows expressed in grammes per hectolitre of absolute alcohol present acidity reckoned as acetic acid, 15 56, aldehydes, 10 65, furfural, 2 55, ethers reckoned as ethyl acetate, 72 03, and higher alcohols, 85 20 These results indicate again a "blend." The whisky is satisfactorily smooth to the palate, its flavour being delicately malty *It is a spirit of good quality* and is well matured.

UNSWEETENED GIN (FIVE STAR)

(BOORD AND SON 115-121, TOOLEY STREET LONDON, S E)

Genuine gin is a highly rectified spirit and therefore contains a very small proportion of those secondary products of alcoholic fermentation which characterise whisky, brandy, and rum The following are the results in regard to secondary products yielded by the sample of gin above described expressed in grammes per hectolitre of absolute alcohol present acidity reckoned as acetic acid, *nil*, aldehydes, 1 78, furfural, *nil*, ethers expressed as ethyl acetate, 37 28, and higher alcohols, 44 60 Thus the total secondary products amount to only 83 66 grammes per hectolitre of absolute alcohol present Further results of analysis were as follows extractives, 0 04 per cent., mineral matter, 0 01 per cent; sugar, *nil*; alcohol, by weight 37 67 per cent., by volume 34 79 per cent, equal to proof spirit 78 50 per cent The spirit is thus correctly described as dry. It is a pure spirit, delicately flavoured, and entirely free from sugar.

ANGOSTURA BITTERS (SEIGERT'S).

(KUHNER, HENDERSON, AND Co., 115, CANNON-STREET, LONDON, E.C.)

The preparation of "Angostura bitters" is well known as a tonic and stomachic and even febrifuge, acting much in the same way as cascarilla, calumba, cinchona, and other bitter barks. Bitters act favourably on digestion by inducing the flow of saliva and of the gastric juice, while their effect on the gastric nerves is to produce a sensation of hunger. They are thus useful for a distinctly medical purpose but their continual use is strongly to be discountenanced. The preparation under examination is a clear red alcoholic extract of cusparia bark. According to our analysis it contained 5·96 per cent. of extractives. The bitter principles are chiefly glucosides, bodies which yield glucose by hydrolysis with dilute acids. In regard to alcoholic strength the following were the results: alcohol, by weight 44·18 per cent., by volume 51·82 per cent., equal to proof spirit 90·81 per cent. Angostura bitters have been the subject of adulteration, but we believe this particular specimen to be free from any suspicion on this head.

"ARABELLA" NATURAL MINERAL WATER.

(ARABELLA, LIMITED, 2A, HAY-HILL, BERKELEY-SQUARE, LONDON, W.)

This is a sulphated water of the Hungarian type drawn from springs near Belgrade which in view of its high degree of mineralisation is not so disagreeable to the taste as might be expected. According to our analysis the following is its composition expressed in grammes per litre: sodium sulphate, 21·08; magnesium sulphate, 15·66; calcium sulphate, 0·50; sodium chloride, 1·40; and sodium carbonate, 1·017; total mineral salts, 39·657. The water has a distinctly alkaline reaction. It is an effective though mild saline purgative.

"VISANUS" DISINFECTANT LIQUID SOAP.

(THE VISANUS COMPANY, 2 AND 4, CARRICK-STREET, GLASGOW)

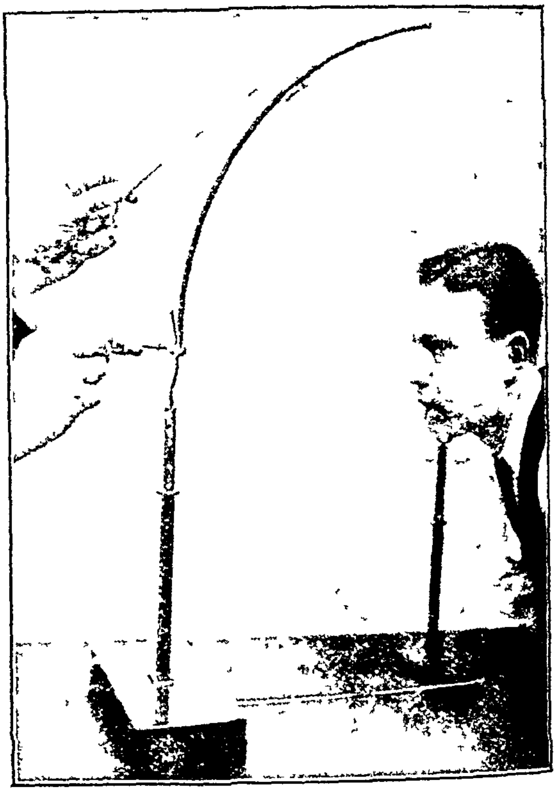
This liquid soap is primarily intended for hospital use, but it is obviously available for other purposes in which the application of an antiseptic and a cleansing agent is desirable. We have examined the preparation and find it to contain an efficient proportion of active germicide. It is perfectly miscible with water and is useful for the disinfection and cleansing of clothes and linen. When properly used it has no injurious action or discolouring effects.

New Inventions.

A NEW PORTABLE PERIMETER.

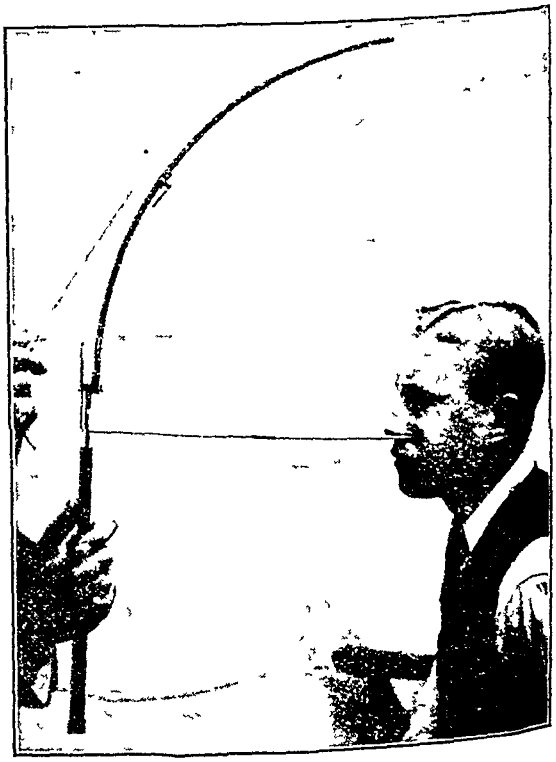
THIS instrument consists of the following parts: 1. Two uprights, to one of which a jointed aluminium arc can be attached, while the other is provided with a rest to support the chin. The uprights are brass tubes which slide within one another and by means of a screw adjustment they can be raised to any convenient height. That which supports the arc fits into a socket on the lid of the box, thus affording complete stability during examination of the visual field. 2. The arc consists of three pieces of aluminium tubing which fit firmly together and form a quadrant of a circle of radius 33 centimetres. The first piece of tubing which springs from the upright is firmly joined to this and cannot be removed. The other two pieces can be readily detached and fit into curved grooves in the lid of the box when the instrument is not in use. 3. The carrier which supports the test object consists of two superposed discs, the anterior of which has an aperture of five millimetres square at its inner margin. The posterior disc can be rotated behind this and the colours white, blue, red, and green placed in succession behind the opening. The carrier itself is moved round the arc by means of a steel wire 10 inches in length in the observer's hand, the movement being very easy and necessitating but little manipulation. 4. A thin metal disc three and a half inches in diameter which can be screwed to the back part of the upright supporting the arc. A point springs from the centre of this disc and there are four clips at its margins to affix the chart. The observer rotates the disc and with it the arc and chart while taking the visual field of the patient.

FIG. 1.



Showing use of perimeter with chin rest.

FIG. 2.



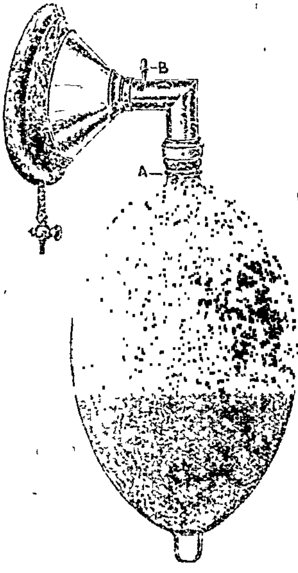
Showing use of perimeter without chin rest.

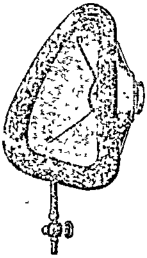
The visual field may be taken with this instrument either with the chin rest or without it. The distance of the patient's eye from the fixation point of the perimeter is measured by means of a steel rod 33 centimetres in length which can be fixed to a hole in the front of the box (if the chin-rest is used) (Fig. 1) or into a hole in the upright which supports the arc one and a half inches below the fixation point of the perimeter if the instrument is used without the chin-rest. The distal end of the rod in the latter case impinges on the patient's cheek while the upright is in the hand of the observer, as shown in the illustration (Fig. 2). With a little practice sufficient steadiness is obtained to take the fixation field in cases of paresis of the ocular muscles, and to measure the angle of a squint without using the chin-rest. It is very useful for examining the visual field in patients confined to bed. The different parts of the instrument fit into a wooden box ten inches long, four and a half inches wide, and two inches in depth. The weight is little and it can readily be carried in a small hand-bag with many other articles. The charts are three and a quarter inches in diameter and are gummed at their upper margins for ready insertion into a notebook. This instrument has been made under my direction by Messrs. Ferrier, 56, Beresford-street, Walworth-road, London, S.E. The workmanship is excellent. The charts are supplied by Messrs. Adlard, Bartholomew-close. The cost is moderate.

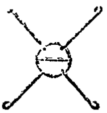
G. T. BROOKSBANK JAMES, F.R.C.S. Eng.,
Assistant Ophthalmic Surgeon, Westminster Hospital;
Assistant Surgeon, Royal Eye Hospital,
Southwark.

THE "IDEAL" INHALER FOR THE ADMINISTRATION OF SOMNOFORM AND ALLIED ANÆSTHETICS.

THIS is the name that has been given by the makers to an apparatus which I have devised and have been using almost daily for over three months. The accompanying illustrations so clearly denote the construction and method that very little further explanation is necessary. Briefly, the chief advantages of this inhaler are as follows:—1. It is simple in construction, unbreakable, and cannot get out of order. 2. The truncated-shaped lint cone being kept in position by a four-armed spring can immediately be removed and replaced at a cost of practically *nil*. 3. By leaving the air valve B open when applying the face-piece the patient is able, however small the quantity of air in the supplemental bag, to take a deep inspiration, which becomes saturated with somnoform in passing through the mask. On closing the valve B after the first inhalation the bag becomes automatically filled, hence obviating the need of removing the face-piece until full narcosis has been obtained. This hastens the induction of anæsthesia and at the same time prevents any waste of the anæsthetic, about half a drachm (2·5 cubic centimetres) of which will usually produce a narcosis of from one to three minutes' duration, according to the temperament of the patient, though more in the form of further doses can be given as required. 4. The supplemental bag is an improvement on the ordinary variety in that it is reversible; hence it is quite a simple matter to keep it thoroughly aseptic, and being made of a new kind of rubber it can be sterilised in boiling water. To release the bag the rubber ring A encircling the neck should be pushed upwards on to the metal collar provided for that purpose. 5. With this inhaler somnoform very advantageously takes the place of nitrous oxide as a preliminary anæsthetic to presenting ether, chloroform, &c. Where ether is selected Clover's ether container should be previously attached. The inhaler can be obtained from the Dental Manufacturing Company, Lexington-street, London, W., who regard so highly the reversible supplemental bag that they are seriously thinking of making gas bags on the same principle.



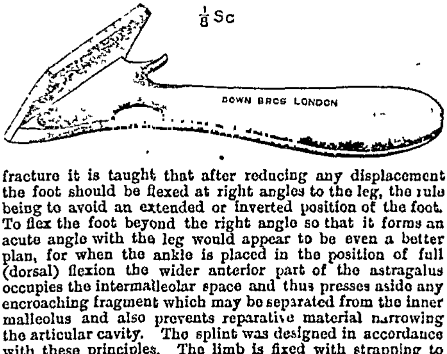




Reading. VERNON KNOWLES, L.D.S. R.C.S. Eng.

A MODIFICATION OF ROUGHTON'S SPLINT FOR POTT'S FRACTURE.

THE accompanying illustration shows a modification that I made in Roughton's splint nearly a year ago and which I now venture to introduce for the treatment of Pott's fracture into the ankle-joint. As in Roughton's pattern, the splint is made of wood and it can be seen to be shaped for the outer side of the leg and foot, the oval fenestra being opposite the external malleolus, but instead of the leg- and foot-pieces being at right angles they together form an acute angle four-fifths of a right angle, and the sole-piece also is fixed at an acute angle with the leg as well as with the foot-piece, the angle in each case being four-fifths of a right angle. In the larger-sized splints the angle of flexion of the foot-piece should be nine-tenths of a right angle. In treating Pott's fracture it is taught that after reducing any displacement the foot should be flexed at right angles to the leg, the rule being to avoid an extended or inverted position of the foot. To flex the foot beyond the right angle so that it forms an acute angle with the leg would appear to be even a better plan, for when the ankle is placed in the position of full (dorsal) flexion the wider anterior part of the astragalus occupies the intermalleolar space and thus presses aside any encroaching fragment which may be separated from the inner malleolus and also prevents reparative material narrowing the articular cavity. The splint was designed in accordance with these principles. The limb is fixed with strapping to the splint, which is evenly padd
bottom foot-piece maintains not
but also inversion. Massage can
on the splint, the knee being well flexed to relax the tendo Achillis, and then, as Pott says, "everything will in general succeed very happily." The splint may be obtained from Messrs. Down Bros., St. Thomas-street, London, S.E.



London. SYDNEY R. SCOTT, B.S. Lond., F.R.C.S. Eng.

THE LEICESTER CREMATORIUM.—The Leicester town council has appointed Dr. C. K. Millard, medical officer of health of the borough, and Dr. Allan Warner, the assistant medical officer, medical referee and deputy medical referee respectively at the Leicester Crematorium. The appointments are made under the provisions of the regulations made by the Home Secretary in pursuance of Section 7 of the Cremation Act, 1902. Before allowing any cremation to take place it will be the duty of the referees to be satisfied that all the requirements of the Cremation Act and the regulations made thereunder have been complied with and that there exists no reason for any further inquiry or examination.

THE LANCET.

LONDON: SATURDAY, AUGUST 1, 1903.

The British Medical Association: The Presidential Address.

Dr. T. D. Griffiths, the President of the British Medical Association, chose for his presidential address the obvious subject, "The Evolution of Antiseptic Surgery," and traced the influence of modern medical knowledge on the progress and advancement of all branches of medicine. It is difficult to deliver a plenary address at such a gathering as the annual meeting of the British Medical Association which practically has not been delivered before, and the President of the Association, the orator in medicine, and the orator in surgery have all had this experience in 1903, and their successors will be in the same plight in future years. The occasion for their words being similar to the occasions that have prompted the words of their predecessors they are bound to go over old ground to some extent. The indications for the address of the President in particular are year by year identical and it follows that every medical man who is called upon to occupy the presidential chair is bound more or less to repeat the phrases of past holders of that dignified position. Dr. Griffiths, we are certain, recognised this fact when he chose so well-worn a theme whereon to address his audience as a description of the evolution and consequences of the practice of antiseptic surgery, but we are of opinion that, as he had more or less to say what others had said before him, he could not have chosen a theme worthier of repetition. The wonderful change that has come over the whole theory and practice of surgery since the comparatively recent days when, working with different objects and on different lines, Lister, Pasteur, and Koch attacked the problems which resulted in the formulation of the antiseptic theory, cannot be too much insisted upon. There are now some two generations of medical men who have been entirely brought up in accordance with antiseptic doctrines, and year by year those born in the modern faith are added to the roll of the profession, while the number of those who received their education before the establishment of those doctrines is sadly dwindling under the onslaughts of time. Therefore, it is well that the story of the evolution of antiseptic surgery should be frequently told—and we may add that Dr. Griffiths tells it with clearness and cogency—for otherwise medical men might forget the significance and importance of the revolution that has been worked in times so near to our own as thirty-five or forty years ago.

An interesting part of Dr. Griffiths's address is that in which he traces the practical application of modern scientific medicine to public health. Here he points out that the majority of thinkers, medical men and laymen alike, are apt to be too optimistic. Sanitary science is a splendid thing, but we, proud of the many practical applications of learned theory to daily use which are comprised under its name, are all inclined to attribute too much to its operation. Dr. Griffiths is, we think, quite justified in saying a warning word, for our public health legislation has not yet justified enormous self-satisfaction. While sanitary science as applied in this country to the lives of the people is responsible for countless benefits to the population our eyes should be open to the equally countless difficulties that attend the administration of the laws regulating State medicine. Whether we are concerned with water-supply, with purity of food, with drainage systems, with accommodation for infectious disease—whatever it may be, we are met with an eternal contest between public and private interests. Upon the whole, in England the public weal prevails and in the end the vested private interest yields, but the progress of the sanitary administration of the country is sorely retarded by constant frictions. As a means of remedying this situation Dr. Griffiths makes the practical suggestion that the power of the medical officers of health of the country should be strengthened and we believe that his proposal will find favour in the eyes of most medical men. He suggests that the county councils should be compelled to appoint county medical officers and that the various urban and rural sanitary districts should be grouped together so that the aggregate of work should be sufficient to constitute a career for a medical officer of health, who must also receive an adequate salary. Dr. Griffiths would entirely do away with the medical officer of health in rural districts who receives £50 for the supervision, which must in most cases be little more than nominal, of a sanitary district comprising as many square miles. No one who has thought over the matter, and certainly no one who has any experience of the conduct of municipal or parochial affairs, can come to any other view than that held by Dr. Griffiths. In the many frictions that occur between public and private interests the medical officer of health should be able to play the part of a strong independent official. To effect this he ought to be placed in an independent position, to be relieved from the responsibilities and ties of private practice, and to be paid properly.

With another suggestion made by Dr. Griffiths with the same end—that of strengthening the sanitary administration of the kingdom—we are also in accord. He desires to see the President of the Local Government Board, in whose department the sanitary administration of the country is vested, placed upon the same footing as the other great Ministers, the Secretary of State for War, the Secretary of State for Foreign Affairs, and the Home Secretary, for example. The present President of the Local Government Board, Mr. Walter Long, enjoys Cabinet rank, but his office is not one that necessarily carries with it a seat in the Cabinet, while a striking difference between his salary and that of the salaries of the great officers of State to whom we have alluded accentuates the mark that is drawn in the official mind between them. We entirely sympathise with the view that the Minister who has charge of the public health of the community ought to be placed in the highest possible public position in the councils of the State. So much is this principle recognised by many medical men that the appointment of a Minister of State for Public Health has been often mooted in our columns and elsewhere. Such a Minister exists in some foreign countries and perhaps the post will be created sooner or later with us, but this is rather a matter for the future. The obvious step forward that should be taken at the present time is to elevate the head of the department of State on whom the duties of a Minister of Public Health fall to a position comparable with that of the heads of the other great departments of State.

The British Medical Association: The Address in Medicine.

IN selecting the infective and infectious diseases as the subject of his Address in Medicine Dr. FREDERICK ROBERTS chose a subject which is well calculated to meet with the approval and to appeal to the diverse tastes of his audience. Indeed, owing to the popular interest which always attaches to the authoritative utterances of the distinguished physicians who year by year are intrusted with these addresses in medicine, and owing to the wide dissemination of the addresses themselves in the lay press, the occasion has been afforded for appealing directly to the public and vindicating the general policy of the medical profession, while certain truths have been enunciated well calculated to impress on governmental, municipal, and sanitary authorities their duties and responsibilities in the safeguarding of the public health.

Dr. ROBERTS takes full advantage of his opportunity and opens the flood-gates of oratory on a subject on which the medical mind is particularly sensitive. In combating and limiting the ravages of infectious disease among all classes of society Dr. ROBERTS points out that our aims are peculiarly single-hearted, disinterested, and beneficent; our efforts, however, in these directions were often traduced by scoffing and slanderous misrepresentation. And in this connexion the conscientious objector, the anti-vivisectionist, and certain other faddists with an "anti" before their descriptive titles come in for a just measure of censure and rebuke. On the other hand, we as a profession are exhorted "never to relax in our efforts to promote the good cause and to encourage, to develop, and to enforce every measure, scientific or practical, which has for its object the mitigation or prevention of disease." In connexion with the attitude of the medical profession in respect of the use and abuse of alcohol, both in conditions of health and of disease, public opinion has recently been stirred by the so-called "International Medical Manifesto" and by the ill-considered and ill-informed vaporings of sensational journals. On this subject Dr. ROBERTS expresses some temperate and rational criticisms. Although, owing to the limitations of his subject, he could not touch on the whole question in its general bearings, nevertheless, so far as the treatment of infectious disease is concerned, his therapeutic postulates entail the discriminating use of moderate quantities of alcohol. He is of opinion that the judicious administration of alcohol has within his own experience been the means of saving many a grave and almost hopeless case from death. This is the sort of positive evidence which takes a great deal of gainsaying. That medical men, both in past times and nowadays, have prescribed alcohol inconsiderately is another matter. The consumption of alcohol in some of our large hospitals has at times been unduly great and no one denies this. But when a physician of Dr. ROBERTS's position testifies to the value of alcohol, properly exhibited, as a life-saving remedy, he is a bold man who resolves in his practice to dispense with its aid.

Although in its more extreme manifestations the author of the address does not appear to be very much in sympathy with the "absurd, irrational, and most mischievous specialism which is so rampant at the present day," nevertheless, as subsidiary to the more ordinary bedside methods which come within the reach of all practical clinicians, he gives full credit to the recent developments, both bacteriological and sero-therapeutic, in the scientific diagnosis and treatment of infectious disorders. At the present day there is an undoubted danger lest the rising generation of practitioners should come to rely too little on their own personal observations and too much on the revelations of the microscope and test tube, and in this connexion Dr. ROBERTS suggests "that while the modern medical student has immense advantages he labours under a decided disadvantage from the point of view of clinical observation, as compared with those of us who served an apprenticeship and became familiar with, at any rate, the more common infectious diseases, even before we started at a medical school." Dr. ROBERTS thus rehabilitates the much debated question of apprenticeship in a novel and interesting fashion, but not, we think, with any serious idea that medical education will ever return to its old course. We know well the many advantages that some apprentices enjoyed; but we know also with many of them their sojourn with a practitioner was the purest waste of time.

The British Medical Association: The Address in Surgery.

THERE is no more obvious subject for the contemplation of members of the British Medical Association than the progress which surgery has made within recent years and Mr. MAYO ROBSON was happy in the choice of this theme, for he himself has taken no small share in the advancement of surgery during the last 30 years. Especially has progress been made in the surgery of the abdomen and on this subject no one is better qualified to speak than the ingenious orator. Thirty years ago there was no abdominal surgery. It is true that a few operations were at rare intervals attempted, such as colotomy, especially the lumbar form, and gastrostomy, but beyond these hardly anything was done. The surgeons of those days were acting rightly in refraining from meddling with abdominal disease, for the results which followed the few operations attempted were, indeed, appalling. Mr. MAYO ROBSON quotes statistics showing that in 1870 in four London hospitals, of 11 cases of ovariotomy nine died. Even the operation for strangulated hernia had a mortality of about 50 per cent. in those cases in which it was considered necessary to open the sac. For nearly all abdominal conditions, which would nowadays at once be submitted to the surgeon no operation was attempted, and the surgeon was practically helpless even in the very few cases in which his aid was sought, for it was never sought until too late.

It was not until the memorable dawning of the new era of antiseptic surgery that it became really allowable to open the abdomen in order to treat some morbid condition contained therein. The wholesome dread of peritonitis, arising they knew not how, deterred the older surgeons from interfering actively with the abdominal viscera even when merely a volvulus of the intestine or a peritoneal band was producing acute obstruction, and they had perforce to content themselves with manipulation, inversion, and succussion. Rarely, very rarely, these manœuvres were attended with success and these occasional successes seemed to justify their employment even in cases in which from our present knowledge it is obvious that nothing but harm could result from such blind and violent methods. The diagnosis was often obscure and, indeed, it cannot be said that we have advanced very far in mere diagnosis, though some distinct progress has been made. At the present time the exact diagnosis is often postponed till the abdomen has been opened and then it is generally quickly made. In this practice there is no little danger of occasional harm resulting, for the more exact the diagnosis previously to the operation the more correctly can the surgeon choose his incision, and the more quickly and easily can he proceed to remedy what is wrong. We would not suggest the postponement for one hour of an operation in order to perfect the diagnosis when an operation is clearly indicated, but there is some risk of exploratory laparotomies being unnecessarily employed.

The progress of abdominal surgery is well illustrated by Mr. MAYO ROBSON by accounts of the operations performed on most of the abdominal viscera, the stomach, the intestines, the kidneys and the ureters, and the uterus, especially in connexion with abnormal gestations, but it is perhaps in the latest achievements of the surgery of the abdomen that interest mainly centres and this is the surgery of the pancreas. This is almost the creation of the last five years. Cysts of the pancreas had previously been opened and drained; now, however, the operations on the pancreas are numerous, and Mr. MAYO ROBSON has himself operated on nearly 100 cases. Acute pancreatitis is a most striking disease; it arises with symptoms closely resembling acute intestinal obstruction and in many cases the abdomen has been opened and no obstruction found, but an acute pancreatitis has been recognised. Recently in some of these cases surgical intervention has been successful and more is to be hoped for in the future. Many cases which have been described as malignant disease of the head of the pancreas have been shown to be cases of chronic pancreatitis and recovery has ensued after drainage of the duct of Wirsung through the bile passages. Calculi of the duct of the pancreas have also been removed, in one case by an incision through the substance of the pancreas. Such modern developments of surgery as these and others quoted by Mr. MAYO ROBSON in his instructive address show not only the extent of the recent work which has been done in the surgery of the abdomen but fill us with hope for the future. At the present time little appears to remain for the surgeon to accomplish, but our experience should teach us that in directions at present undreamt of surgical activity will achieve triumphs which may dwarf what has hitherto been accomplished. It is only reasonable to expect rapid advance

Annotations.

"Ne quid nimis."

ANOMALOUS SMALL-POX AND ITS LESSONS.

THE variations in type which communicable diseases are liable from time to time to assume are eminently interesting from the point of view of the epidemiologist, but for the administrator such vagaries are not unlikely to give rise to awkward predicaments, resulting in some instances in unfounded charges and undeserved rebukes. The public are so accustomed to dogmatic statements that they are prone to attribute hesitation on the part of a medical man to ignorance rather than to accumulated wisdom. An instance of this nature has for a considerable time been before us at Trinidad, where a disease which has presented unusual symptoms, and which has since manifested more distinct features of small-pox, has puzzled the medical profession of the island for many months. Recently, too, phenomena of a somewhat anomalous nature have occupied the attention of the medical profession at home, more especially in Nottinghamshire and at Cambridge. In each instance much excitement has been occasioned and columns of the local press have been devoted to public discussion of the subject. Much of this undue disturbance is the result partly of the demand on the part of the public for a precision of knowledge which the facts do not justify and partly of a tendency on the part of the medical profession itself to meet that demand by a certainty of diagnosis which is not always supported by evidence. It is obviously difficult to diagnose that which has neither been described nor seen, and it would be unreasonable to make the medical profession responsible for what may not inaptly be termed a freak of nature. All that can be fairly asked is that reasonable precaution shall be exercised and that where a doubt exists the action taken in consequence of such doubt shall be that dictated by the first principles of preventive medicine—i.e., that the public safety should always receive the benefit of that doubt and that a disease which may not improbably prove to be small-pox should, so far as preventive measures are concerned, be treated as if it were small-pox. Although the number of cases of small-pox has increased within the last few years it is still true that the majority of medical practitioners have never seen a case of the disease, much less such a selection of cases as would enable them to make a correct diagnosis in the face of anomalous symptoms. But it has to be borne in mind that there are now many medical men who are familiar with the disease and whose opinion in a case of doubt would be of the greatest value. The services of such experts can be easily procured, and the sanitary authority which hesitates to procure such advice on the score of expense does not show a high appreciation of its responsibilities. Judging from recent events which we have no need to particularise it seems to us that it is very desirable to make public a doubt rather than to proclaim a definite opinion which the facts are insufficient to justify. This is more especially the case when the dogmatism is likely to involve a serious risk to the public health and discredit to responsible public officials. In endeavouring to arrive at a conclusion in the case of a disease such as small-pox the greater the number of cases which can be examined the smaller the margin of error, and it is possible by examining a number of cases to obtain, as it were, a complete type of the disease. If photographs of the cases occurring in Trinidad and other places are examined it is possible to select from each group some which are absolutely anomalous and others which are absolutely typical, and we cannot but infer that were a sufficiency of cases seen in each instance there would be less liability to mistake. Wherever there is the least doubt isolation should be practised and vaccination or revaccination at once carried out and the public will learn in time to appreciate the fact that preventive medicine acts upon doubts as well as upon certainties. In this connexion we would appeal to the lay press, upon which many of the public rely solely for their information upon all subjects, not to make absolutely unfounded statements. For instance, a paragraph recently appeared in a London morning paper in which Dr. S. Monckton Copeman was credited with having said that the Cambridge epidemic was neither chicken-pox nor small-pox but a complaint hitherto unidentified. As a matter of fact Dr. Copeman never said any such thing. Incorrect statements such as this are dangerous in that they lead the "man in the street" to neglect precautions, above all that of vaccination.

THE HEALTH OF THE ARMY.

IN an annotation in THE LANCET of July 25th, p. 246, we dealt with the special memorandum issued by Sir William Taylor, Director-General of the Army Medical Service, in regard to the deterioration of physique said to be observed among intending recruits. We are not, however, desirous of discussing here the significance of the memorandum, except in so far as it raises suspicions as to the fitness of the men actually accepted. There appeared recently the Army Medical Department Report for 1901 and from this we learn that in the army as existing on a peace footing the mortality-rate for the United Kingdom was 4·71 per 1000. For the last eight years the rates under similar conditions in the armies of continental powers have been: France, 4·58 per 1000; Italy, 4·87 per 1000; and Russia, 5·32 per 1000, so that it will be seen that our British results are nothing much to boast of. The figures given for France are not regarded with any special satisfaction in that country and Dr. Granjux has been seeking to elucidate the influences to which they are to be attributed. He finds that the rate ranges from 3·61 for the "ouvriers d'artillerie" to 7·88 in the case of the "infirmiers" who may be taken as corresponding roughly to our hospital orderlies. These figures are, he believes, to be correlated with the facts that the artillery workmen are usually volunteers and pursue their avocation in well-ventilated shops, while the men in the second category are exposed to the risks incidental to insanitary conditions and contagion. Our own army returns show a minimum rate of 3·51 for the Household Cavalry and a maximum of 7·92 for the regimental depôts, while the figures for the garrison staff and departments are also high, being 5·63. Causes somewhat similar to those mentioned in connexion with French soldiers may therefore be traced in the case of the British. It will be noticed that the figures for the German army are not given above. They are said to be only 2·32 per 1000, a fact which "gives furiously to think." The difference, as compared with France, is declared to be due to the differences in the birth-rate, and consequently in population, of the two countries. Each keeps up a huge standing army, but as the resources of Germany are larger she has not to enforce conscription with the same thoroughness as is necessary in France and therefore doubtful material has not to be utilised to the same extent. But what explanation is to be advanced in regard to British troops? An inquiry dealing with this point might well be undertaken by the Commission which Sir William Taylor suggests should, with the advice of the Royal Colleges of Physicians of London and Surgeons of England, be appointed to consider the question of recruiting. In a letter to us, which has also been communicated to the lay press, the Duke of Wellington, who is President of the National Service League, points out that a fairly accurate indication of the improvement or the reverse of the physique of an army can be obtained by taking statistics relating to a long series of years. "Nor is it possible," he says, "to escape the conclusion that if the physical standard of an army is improving or deteriorating it must be at least to some extent a barometric indication of a similar tendency in the national physique." It must not, of course, be forgotten that in this country our army recruits are taken for the most part from the unskilled labouring classes, while in countries where conscription is in force the army represents all classes of the population. But even taking this fact into consideration, the Duke of Wellington states that statistics show an undoubted tendency to deterioration in the physique of recruits and in the health and stamina of our army as compared with that of Germany.

COMPLIMENTARY DINNER TO MR. JONATHAN HUTCHINSON.

Sir H. Greenway Howse presided on July 23rd at the complimentary dinner given at the Trocadéro Restaurant in honour of Mr. Jonathan Hutchinson. Covers were laid for 154 guests. At the high table to the right of the chairman were seated Mr. Jonathan Hutchinson, Dr. Robert Barnes, Sir J. Fayrer, Mr. W. H. M. Christie, Dr. G. W. Potter, Rev. T. R. R. Stebbing, Dr. R. Farquharson, Sir John Tyler, and Mr. Andrew Clark; to the left were seated Sir Thomas Barlow, Sir Henry Burdett, Sir Anderson Critchett, Dr. Theodore Williams, Sir Alfred Cooper, Professor Adami, Dr. G. A. Heron, and Mr. H. T. Butlin. Letters regretting their inability to attend were received from Lord Strathcona, the Attorney-General, Sir R. Douglas Powell, Sir T. Lauder Brunton, Sir Henry Thompson, Sir William H. Broadbent, Professor T. Clifford Allbutt, Dr. Peter Horrocks, Mr. F. Eve, and others. Sir H. G. Howse, in proposing the health of Mr. Jonathan Hutchinson, said that when he (Sir Henry Howse) entered the profession in 1861 the name of Mr. Hutchinson was then fully before the medical profession. Referring to the journeys which Mr. Hutchinson had made in South Africa and India, Sir Henry Howse asked who amongst them at the age of 73 years would care to undertake long and arduous journeys in search of facts which might support or might damn some hypothesis of interest to the profession. He thought that such a record was most remarkable. He would remind them that that dinner was held on the seventy-fifth birthday of Mr. Hutchinson. Mr. Hutchinson had always taken great interest in medical studies and also in public matters, for when the London County Council put forward its proposition to open Lincoln's Inn Fields Mr. Hutchinson persuaded the Council of the Royal College of Surgeons of England to abandon its attitude of opposition to the scheme and to help it forward. Sir Joseph Fayrer, who also spoke to the toast, remarked that he always read Mr. Hutchinson's books with profit and had learnt to look upon him with profound respect. What had struck him as most deserving of imitation was the energy with which Mr. Hutchinson had pursued his studies up to his seventy-fifth year with fidelity of conscience and with the true scientific spirit, always striving to ascertain what was right simply for the sake of right. He (the speaker) had been asked to refer to what Mr. Hutchinson had done for the colonies and he wished to express the gratitude of those young men who had come from the colonies. Sir Joseph Fayrer concluded by regretting that no public honour had been bestowed on Mr. Hutchinson. Mr. Hutchinson, in thanking those present for the cordial way in which they had drunk his health, referred to the healthy feeling of pride which he experienced in knowing that he had gained the esteem of so many influential friends. Such recognition helped him on in his work and he thanked Sir Joseph Fayrer for mentioning fidelity of conscience. He was willing to claim fidelity of conscience because he had been brought up in the society of Quakers, amongst whom the one dogma was conscience. Turning to the question of leprosy Mr. Hutchinson related how when visiting Robben Island he saw over 500 persons confined for life because of the inattention of the medical profession to facts. In his opinion leprosy was not contagious and yet on Robben Island there were confined the children of white parents condemned to association with Hottentots and Kaffirs, and he contended that therein lay a motive for work for what remained of his life—to render the medical profession alive to its duty in regard to leprosy. In the course of his concluding remarks Mr. Hutchinson said that he believed poetry inspired him with motives for dry scientific work and he had always tried to act up to the motto of the German poet, "Keep true to the dream of your youth." The toast of "Our Guests" was given by Sir Thomas Barlow who said that their presence there was in honour of one who had given a rare example of unremitting labour and practical enthusiasm not only in surgery and pathology but also in the cause of education. There was thus a special fitness in what he called the eclectic character of the gathering that evening in honour of Mr. Hutchinson. The toast was acknowledged by Mr. Christie, the Astronomer Royal, and the company separated after the chairman had responded to the toast of his health proposed by Sir Alfred Cooper.

THE DANGERS OF THE HANSOM CAB.

THERE seems to be but one limit to the extent of the casualties for which the hansom cab may be responsible. That limit is the fortunate circumstance that these vehicles usually carry only two persons besides the driver. We are led once more to animadvert upon the many and dangerous defects of the "two-wheeled hackney coach" by the tragedy that occurred in Piccadilly on July 26th. It will be remembered that on that day a hansom cab horse bolted, that the driver was flung from the box against the railings of St. James's Church, sustaining so severe a fracture of the skull that he died very shortly after, and that of the two occupants one met with a fate similar to that of the driver, while the other is still in St. George's Hospital under treatment for fracture of the anterior and middle fossæ of the base of the skull and fracture of the lower jaw. It may be inferred that the bolting of the horse is no fault of the hansom cab. Even this is only true to a certain extent, for according to some accounts of this accident the horse previously to bolting had slipped several times on the wood pavement. This, no doubt, unsettled the horse's nerves, for there is no animal so prone to fits of unreasoning terror as a horse. Moreover, owing to the arrangement of a hansom cab and to the leverage which it exerts, should the horse slip it is only able to recover itself with great difficulty. The chances, too, of danger to those inside the vehicle should any accident occur to the horse are much greater in the case of the hansom cab than in that of any other kind of carriage in common use. A hansom cab is easily upset, is difficult to get out of, and is so constructed as to inflict a maximum of damage upon those inside should the vehicle be overturned or be violently jolted. In the latter case, not to mention severe contusion or fracture of the legs, there is the risk of being guillotined, or at the least partially scalped, by means of the edge of the folded window. This is no mere fanciful idea. It is not long since Mr. Chamberlain illustrated in his own person a mild form of the latter accident, of which we have seen in a London hospital an extreme example. In this case the cab-horse fell, the occupant's hat flew off, and the top of his head coming violently into contact with the window, which was "up," the scalp was split across almost from ear to ear and the unfortunate victim reached hospital with the anterior portion hanging over his face. When it is remembered with what peculiar difficulty a hansom cab is entered, how if there be mud some of this is almost inevitably brushed from the wheel on to the coat or skirt of him or her who enters, and that besides actual dangers the hansom cab is thus beset with minor inconveniences, it may well be wondered how it is that this form of public conveyance retains its place in the public use, if not in the public esteem. A hansom cab which minimised certain of these inconveniences was described in THE LANCET of May 9th, p. 1311. If the four-wheeled cab were but further improved—it has made some strides of recent years—and particularly if it could be easily converted into an open carriage in fine weather, we feel certain that the number of hansom cabs and with it the number of cab accidents would speedily be reduced—a "consummation devoutly to be wished."

POOR-LAW GUARDIANS AND VACCINATION FEES.

THE Vaccination Act of 1898 produced considerable modifications in the duties of public vaccinators, chiefly in the direction of increasing the amount of attention that was thenceforth to be given to individual cases, and in other respects it made a variety of important changes in the system which had previously been in operation. Vaccination stations were abolished and instead of the children being taken to the public vaccinator he was required to attend at their homes in the event of the parents preferring this course. Only glycerinated calf lymph was to be used and attention to antiseptic methods became essential. It was easy to foresee that this multiplication of duties would involve additional expenditure and our columns have on many occasions borne witness to the annoyance felt by boards of guardians at the increased outlay under the head of vaccination fees since the beginning of the year 1899. By the Vaccination Order of 1898 the Local Government Board fixed a maximum and a minimum charge for the operation, and during the last two or three years a number of boards of guardians have, by adopting resolutions and otherwise, expressed their anxiety to have the official scale of fees reduced. To take a comparatively recent instance, the Wigan board of guardians at a meeting held last May had before them a return extending over several years and showing that the fees payable to public vaccinators were £222 for the half-year ended Michaelmas, 1898, and £212 for the half-year ended Lady-day, 1899, while they were £1069 for the half-year ended Michaelmas, 1902, and £935 for the half-year ended Lady-day, 1903. The guardians resolved to prepare a memorial to the Local Government Board, calling attention to these facts, praying for the issue of a new Vaccination Order with a reduced scale of fees, and suggesting that the fee should be 2*s*. 6*d*. for successful primary vaccination or revaccination at the home of the person vaccinated and 1*s*. 6*d*. for successful primary vaccination of any person other than a child at the surgery or for revaccination at the surgery. In support of this proposal the guardians asserted that the above charges were quite as high as an ordinary country practitioner would make to his patients, but this statement is inaccurate and misleading, for the Wigan Medical Guild some years ago passed a motion to the effect that the minimum fee for vaccination at the surgery should be 2*s*. 6*d*. The usual fee for vaccination at home is 5*s*., but among the working classes vaccination at home is not often asked for. Now what has the public vaccinator to do for the 5*s*., or at most 6*s*., which he receives? From the list supplied by the vaccination officer he has to advise by letter or post-card the day on which he proposes to visit and to vaccinate. If the parents are out he has his journey for nothing. If there is epidemic disease in the house he has to postpone the operation and to communicate with the medical officer of health. If the child is in and the parents are willing to have the operation performed he has to render the arm aseptic, to vaccinate, to put on an aseptic pad, and on the eighth day following he has to pay a second visit and if there is any inflammation about the arm he has to treat it. He has then to make entries in his books, to sign certificates, and to send them to the vaccination officer. It must be remembered also that he has to make many futile visits, owing to changes of residence, absences from home, and sickness. We trust that the Local Government Board will give no encouragement to this proposed lowering of the remuneration for what is in reality very responsible work very efficiently performed.

THE RELATIVE MERITS OF A CHEMICAL AND BACTERIOLOGICAL EXAMINATION OF WATER

OWING mainly to the recent pollution of the river derived water supplies of the metropolis by the floods, the question has been raised once again as to the relative value of the chemical and bacteriological analysis of water for drinking purposes. It may be useful, therefore, to summarise the position which both methods of examination at present occupy in their bearing upon the detection of pollution. The view that the chemical composition of the water always bears a direct relation to the number of micro-organisms receives very little support unfortunately, from a very large number of experiments that have been made in this direction. It is true that frequently a large number of bacteria is associated with an excess of solid matters, but the same chemical conditions may be found to exist when the number of organisms has diminished to vanishing point. Conversely a water with little or no solid matter may show a considerable number of organisms. Again, there is little doubt that the detection of actual sewage contamination by bacteriological methods is much more delicate and definite than that offered by chemical analysis, though it may not be possible to identify the specific organism. In the case of the typhoid fever outbreak at Maidstone, for example, a bacteriological examination of the infected water made about ten days after the specific infection had taken place failed to demonstrate the existence of the bacillus typhosus, yet there was no doubt at all about the bacillus coli being present. In the Worthing epidemic, again, the specific organism of typhoid fever was not detected in the infected water supply, although the presence of the bacillus coli was readily discovered. It has, in fact, been shown that a recent contamination of a water supply by sewage can easily be detected by bacteriological means even when the pollution is so slight as one part per million, a microscopic degree of pollution which it is very doubtful chemical methods would be able to detect or at any rate to such an extent as to allow of an exact diagnosis being made. The value of bacteriological analysis was largely discounted in the early days of bacteriology by the fact that the number of bacteria was regarded as a basis of decision, while no attention was paid to the determination of the species of bacteria present in drinking water. It is this latter departure in the bacteriological examination of water which has rendered great service in enabling a definite conclusion by bacteriological methods to be drawn as to whether or not a water is polluted. Thus the position is best summed up by saying that whereas chemical analysis may be of value when an exact quantitative analysis is made, in the case of the bacteriological method the analysis should be decidedly qualitative. The two methods, strictly speaking, should go hand in hand, for each is helpful to the other in elucidating the exact history of the water in question. It is well to bear in mind, however, that the purification of water by filtration through sand is essentially a biological process and hence the purifying efficiency of the filtering bed from a pathogenic point of view can only be ascertained by resorting to bacteriological methods of examination. Micro-organisms and not chemical substances are, after all, the real *materies morbi*, and though the presence of chemical substances may, of course, indicate impurity, yet it may not follow that it is of a specifically dangerous kind.

THE DEMONOLOGY OF THE NEW TESTAMENT

IN the July number of the monthly paper of the Guild of St. Luke appears an article by Surgeon Colonel F. H. Welch upon the above subject. Demoniac possession is a favourite subject for discussion for it embraces a certain part of the two sciences of medicine and of theology. But our knowledge of mental processes is exceedingly vague and no one can say how we think. In some cases of insanity or of defective mental process there is some obvious gross lesion, but in how many others is there nothing of the kind? Surgeon Colonel Welch's conclusion is as follows: "I throw in my lot with those who regard demoniac possession as but an expression of old world ignorance, and these examples in the New Testament as but illustrations of mental disorder—insanity in one or other form—clothed in the phraseology and indicative of the beliefs of that day." He allows that with regard to Our Lord's treatment of such cases "there seems no resting ground between denying the Gospel narrative and acknowledging the outcome as miraculous as viewed by our present knowledge and experience." But he goes on to say that possibly an ampler knowledge of the laws of God and Nature in the distant future will remove all these disease cures from the sphere of miracles as now understood by us. This is quite possible, but at present so far as we can see the question is insoluble. It is not of much help to say that the demoniac possession of the New Testament is insanity, for then arises the further question, What is insanity? It cannot be denied that there are forces, both physical and psychical, of which we know little or nothing. A few years ago radio activity was unknown, and in the domain of psychic forces strange things happen "east of Suez" and in out-of-the-way parts of Africa—witness Captain Wellby's experience in Abyssinia upon which we commented in THE LANCET.[1]

DYSPNŒA AFTER REMOVAL OF A TRACHEOTOMY TUBE.

ONE of the most troublesome of the after effects of tracheotomy is the difficulty which is often experienced in removing permanently the tracheotomy tube. The child, for this complication is practically only seen in children, is often able to dispense with the tube for some hours, but suddenly great dyspnœa occurs and if the tube is not re-inserted death may ensue. This dyspnœa may occur during the waking hours, but it is especially prone to appear during sleep, the difficulty of breathing awakening the child. In the production of this dyspnœa two distinct factors seem to be involved. One effect of the long continuance of a tube in the trachea is that it leads to the formation of granulations around the edges of the opening into the air tube and wherever the tube touches the mucous membrane. These granulations offer obstruction to the inflow of air when the tube is not in position, but the insertion of the tube tends to push them aside. Later there may be a true stenosis of the trachea from the contraction produced by the cicatrisation. The other element in the production of the dyspnœa is spasm of the glottis. So long as the tracheotomy tube is in position there is no need for the glottis to be kept open for breathing and therefore, as it has been well put, the usual rhythm of the laryngeal muscles has been interrupted by the enforced cessation of all exercise of function in the larynx due to the tracheotomy. When the tube is removed there is great liability to the production of irregular laryngeal spasm and this is especially likely to occur during sleep, for during the time the child is awake his attention is directed to keeping the glottis in an open position for inspiration, but when the child is asleep this voluntary assistance is withdrawn and the glottis may close. In many cases of dyspnœa after the removal of a tracheotomy tube both these causes share in its production. The principles of treatment of this condition are, in the first place, to take care that the tube is not retained longer than is really necessary, for the stenosis and the muscular spasm are both more likely to develop the longer the tracheotomy tube is employed. In the second place, the spasm tends to pass off as the glottis becomes again active, so that the best plan is to leave out the tube as much as possible, care being taken that it can be re-inserted as soon as necessity arises. This can only be done by having the child watched continuously during the first few nights after the removal of the tube. If granulations are present they must be treated either by removal or by the application of suitable astringents. A very interesting case of dyspnœa after removal of a tracheotomy tube was published in THE LANCET of July 25th, p. 225; in this case intubation was successfully employed to overcome the difficulty of breathing.

---

[1] THE LANCET, Sept. 9th, 1899, p. 731.

THE GOAT AS A PREVENTIVE OF DISEASE.

THE somewhat startling news that the lower classes of Cambridge are trusting to the presence of a goat to protect them and their houses from the infection of small-pox is only another proof that primitive barbarism dies out very slowly even under the shadow of colleges and laboratories dedicated to the highest forms of scientific research. The Cambridge dairyman who sends his goat into and round the dwellings of his neighbours in the area infected by small-pox along the Newmarket-road is said to be giving expression to a rooted local belief. Indeed, he has only extended to human beings the universally-found rustic superstition that goats bring good luck and insure the health of cows and other animals. It is common in Lincolnshire, for instance, to keep a goat on the ground of its being "healthy for cattle." Among old-fashioned cattle-men in Virginia the goat is held to be a preventive of disease and a clearer-away of noxious herbs. In Ulster a goat grazes among the cows of the small farmers in order to bring good luck and to eat poisonous weeds, and on many large dairy farms in the south of England a goat or donkey is sent out with the herd in order, as avowed, to prevent premature calving. Finally, in large London stables a goat is often kept either to lead the horses out in case of fire or for no reason at all. Why are goats kept? and what is their use? A writer in *Notes and Queries*, where the question of the "Goat and Folk-lore" was discussed some years ago, was inclined to the belief that the goat's effluvium kills microbes. But he was met by the objection that *a fortiori* the pig would be the better antiseptic agent of the two. The argument was fallacious, yet the goat is not a microbe-killer. It is probable that his luckiness and health-giving properties have a pagan origin and that he remains symbolically a relic of the days of witchcraft. The witches of the Walpurgis-night rode on goats who were devils in disguise, and "it is possible that goats are placed amongst other cattle because the witches will not hurt animals which are under the protection of their friends." Whatever excuses and explanations are urged nowadays the goat remains a creature of the black art, just as the cuckoo, who still figures in the oaths of German peasants ("*der Kuckuck soll es holen!*"), is properly the bird of (1) the Devil; (2) Woden; and (3) Indra. The goat, by-the-bye, appears in Scandinavian mythology as the carriage-horse of Thor.

THE PROFESSORSHIP OF SURGERY AT THE UNIVERSITY OF CAMBRIDGE.

ON July 27th Mr. Howard Marsh, F.R.C.S., was elected to the chair of professor of surgery in the University of Cambridge in succession to the late Sir George Murray Humphry. Since the death of the late professor seven years ago the professorship has been suspended. We offer our sincere congratulations to Mr. Howard Marsh upon the honour which has fallen to his lot in being chosen to fill such a dignified and responsible post. At the same time we understand that though it is incumbent upon the professor to be in residence during term, Mr. Howard Marsh intends to continue much of his London work, although he will no longer be a member of the active staff of St. Bartholomew's Hospital.

A DANGEROUS PAMPHLET.

WE have received from a medical man a pamphlet entitled "Opium Smoking as a Therapeutic Power according to the Latest Medical Authorities" which had been placed in the hands of one of his patients. It bears on the cover an advertisement of a firm of dispensing and family druggists—Messrs. Gamble and Company, of 4, Edwardes-terrace, Kensington-road, Kensington, W.—and consists of a detailed description of a pipe for opium smoking supplied by this firm, and minute directions for its use. It is difficult to imagine a more pernicious or dangerous document, the avowed object being to encourage the use of opium by patients without any medical supervision in a variety of ailments and in a seductive form in which they are liable to lose sight of the fact that they are drugging themselves until, perhaps, a permanent habit has been acquired. The list of diseases for which this opium-smoking is suggested in this pamphlet comprises, amongst others, all neuralgias, coryza, sciatica, lead colic, pneumonia, peritonitis, "spasmodic attacks of asthmatic breathing affecting patients with kidney disease," gastralgia, "the fidgets," excessive fatigue, excitement, and sleeplessness. The effects and indications for use are described in quasi-scientific terms and one or two authorities are quoted. It is, moreover, stated that a dangerous intoxication by opium vapour cannot be reached by the smoker at his will, and the use of the drug in this manner is referred to as "this splendid and safe therapeutic agent." The little reverses which happen to beginners are described and directions are given how to overcome or to avoid them. The apparatus, which is somewhat complicated, is made up in sets, and an italicised note at the end of the pamphlet states, "these sets of apparatus and sterilised extract have been supplied to many patients for several years past and have been sent by Gamble and Co. to all parts of the world." The pamphlet is dated 1886 and has thus been in circulation for 17 years and is presumably still distributed. We have no intention to decry the use of opium in the form of inhalation as a therapeutic agent when recommended after due deliberation by a medical man, although it is little used in this country, but the irresponsible advertisement by druggists comparable to that of a patent medicine is on all grounds most strongly to be deprecated. That opium is a very useful remedy in some of the diseases mentioned is, of course, an undoubted fact, but there are few medical men who would order opium in any form for neuralgia or for asthma, more especially the asthmatic dyspnœa of chronic renal disease, without very careful consideration of the dangers, while its use in lead colic or in some forms of abdominal disease and peritonitis may be more immediately harmful. No better example of the evils of the present extensive advertisement of medical preparations, proprietary and otherwise, without any restriction is needed and we hope that the firm of druggists above mentioned will at once withdraw so improper a document from circulation if they have not already done so.

THE DISTRIBUTION OF PLAGUE.

As regards the Cape Colony the medical officer states that for the week ending July 4th the condition of the various places mentioned below was as follows. At Port Elizabeth 1 case of plague was discovered during the week—namely, 1 native male on June 29th. At the Plague Hospital 1 native male died, leaving 6 cases under treatment. Plague-infected rats continued to be found in the town. At East London no case of plague was discovered. At the Plague Hospital no patients died or were discharged during the week; 5 cases remained under treatment. At King William's Town no case of plague was discovered. At the Plague Hospital no patients died or were discharged during the week; 5 cases remained under treatment. Plague-infected rats continued to be found in the town and were also found in the village of Kei-road. At Graaff-Reinet and also at Burghersdorp no case of plague and no plague-infected rats were found. At Queenstown *a native male who died with symptoms of pneumonia on* June 25th has since been found to have suffered from plague. During the week 3 cases of plague were discovered—namely, 2 native males and 1 native female, all of whom died. At Stockenstroom and also at Riversdale no case of plague in man or animals was discovered. As regards Hong-Kong the Colonial Office has received information that for the week ending July 18th there were 18 cases of plague and 9 deaths from the disease, while for the week ending July 25th there were 13 cases and 11 deaths. As regards Mauritius the Colonial Office has received information that for the week ending July 23rd there were 4 cases of plague and 3 deaths from the disease.

ST. BARTHOLOMEW'S HOSPITAL.

THE report of the Mansion House committee, a committee nominated by the Lord Mayor in pursuance of a resolution passed at a meeting of the appeal committee of the governors of the hospital held at the Mansion House on Jan. 19th, has just been published. The committee has come to the following conclusions. With regard to removing the hospital from its present site it considers that it is impossible in the public interest to entertain such an idea. With regard to the buildings the committee states that it is satisfied that important additions to, and a considerable rearrangement and improvement of, the existing buildings are necessary and it considers that with the additional land purchased from Christ's Hospital there will be ample room for the provision of a hospital with every modern appliance. The method proposed is that of a gradual building scheme under which the improvements and alterations contemplated can be secured as soon as funds are obtained. With regard to the financial position of the hospital the committee states that the evidence showed that its properties and revenues are judiciously and economically administered and that the cost per bed compares favourably with that of other hospitals, but it also finds that it is impossible to hope that funds for the additions to, and rearrangement of, the hospital can be obtained from the resources of the hospital itself. It therefore considers that the governors of St. Bartholomew's Hospital are fully justified in appealing to the public for assistance and it heartily commends this appeal to the consideration of the citizens of London and of the public generally. The committee does not think that it would be justified in concluding its functions without placing upon record its opinion that from the evidence brought before it the administration of the hospital has been conducted by the governors in a wise and enlightened spirit with due regard to economy and in the best interests of the patients.

THE INDIAN MEDICAL SERVICE.

WE are glad to receive official information to the effect that proposals for improving the pay and general condition of the Indian Medical Service have now been formulated by the Government of India and that they will shortly be taken into consideration by the Secretary of State for India in Council. It is hoped that the revised terms will be published in September.

WITH reference to the annotation under the heading "Insanity and Racial Fecundity" published in THE LANCET of June 20th, p. 1757, we have been informed that Dr. John Macpherson fell into an error in quoting some of the figures given in his article as he counted the lunatics (as distinguished from idiots) twice over in his total. He gave the numbers of all lunatics and idiots under official cognisance in Ireland as 28,187 in 1881, 36,133 in 1891, and 44,884 in 1901, but the correct numbers were 18,413 in 1881, 21,188 in 1891, and 25,050 in 1901.

THE Royal Medical and *Chirurgical Society's Library will* be closed during the whole of the month of August for necessary cleaning.

Dr. H. E. W. Hoffmeister has been appointed by Princess Henry of Battenberg Surgeon-in-Ordinary to Her Royal Highness.

HOME FOR PATIENTS SUFFERING FROM LUPUS.—An interesting work is being done in the Mile End-road by Mrs. Freeman. This lady has rented the upper part of a house and has a set of comfortable rooms for poor patients who are suffering from lupus and who are undergoing the Finsen light treatment at the London Hospital. Mrs. Freeman is to be commended for the earnest way in which she has undertaken this responsibility and we hope that friends will be forthcoming to enable her to carry on the work that she has so well begun. At the low rate of charge that is made for board and lodging it is impossible to cover expenses, therefore Mrs. Freeman appeals to the generosity of the public.

DONATIONS AND BEQUESTS.—The executors of the late Mr. Richard Bishop have allotted £500 to the Chelsea Hospital for Women, £300 to the building fund of the North-Eastern Hospital for Children, Hackney, and £300 to the Hampstead General Hospital.—Under the will of Mr. A. A. Haclin the sum of £800 is bequeathed to each of the following hospitals: King's College Hospital, Great Northern Central Hospital, Middlesex Hospital, University College Hospital, Royal Free Hospital, French Hospital and Dispensary, London Temperance Hospital, Central London Ophthalmic Hospital, Westminster Hospital, St. Mary's Hospital, Hospital for Consumption, Brompton, Charing Cross Hospital, London Hospital, Cancer Hospital, Brompton, St. Thomas's Hospital, and St. Bartholomew's Hospital.—Mr. Charles Lucena of Westwick, Easthampstead, has by his will bequeathed £200 to the Royal Berkshire Hospital and £200 to the Home for the Dying at Clapham.—By the will of Mr. M. W. Hughes of Dublin a sum of £500 has been left to each of the following hospitals: St. Vincent's Hospital, Dublin; Mater Misericordiæ Hospital, Dublin; Jervis-street Hospital, Dublin; St. Michael's Hospital, Kingstown; City of Dublin Hospital; Meath Hospital, Dublin; Sir Patrick Dun's Hospital, Dublin; the Fever Hospital and House of Recovery, Dublin; Dr. Steevens' Hospital, Dublin; and the Mercers' Hospital, Dublin.

THE
CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

(FROM A SPECIAL CORRESPONDENT.)

(Concluded from p. 256.)

THE proceedings of this Congress, which commenced on July 15th, came to a close on July 21st.

III.—SECTION OF BACTERIOLOGY AND COMPARATIVE PATHOLOGY.

An important discussion upon

A Uniform Scheme of Examination to be adopted in the Bacterioscopic Analysis of Water

was initiated by Dr. SAVAGE (medical officer of health of Colchester) who dealt with the subject under four headings —viz., (1) the collection and transmission of the samples; (2) the data to be ascertained; (3) the processes and procedures of the examination; and (4) the interpretation of the results. With regard to (1) he detailed the precautions usually adopted, but stated that he was by no means sure that ice-packing preserved the bacterial content unaltered. As regards (2) he suggested (*a*) number of aerobic organisms per cubic centimetre developing at low temperature—e.g., room temperature to 22° C.; (*b*) number of aerobic organisms per cubic centimetre developing at 37° C.; (*c*) investigation as to the presence of certain organisms especially liable to be associated with sewage or fæcal contamination, such as bacillus coli communis, bacillus enteritidis sporogenes, streptococci, and proteus organisms; and (*d*) examination for bacillus typhosus and spirillum choleræ. As regards (3) he thought that some uniformity might be come to concerning the temperature of incubation, date of counting the colonies, and reaction of the culture medium, but he did not consider they were yet in a position to suggest a standard method for the qualitative examination for bacillus coli and for bacillus enteritidis sporogenes; it had yet to be determined whether cultural characters alone were sufficient or whether the inoculation test in addition was necessary. He was averse to setting up arbitrary standards as the kind of water under examination was of importance, but with uniformity of methods it was possible to have very satisfactory standards for the different classes of water. In conclusion, he advocated the formation of a committee to consider the question.

Dr. G. LESLIE EASTES (London) thought that there was urgent need for the standardisation of methods and that the time was ripe for some agreement to be come to among bacteriologists. He pointed out the differences obtained by using plain gelatin and nutrient gelatin as a plating medium and then discussed the methods for the isolation of bacillus coli, of which he considered Pakes's glucose formate broth the most delicate and satisfactory.

Mr. F. J. TANNER (Bournemouth) considered that some uniformity in method and procedure was urgently required and that the necessity of periodical and futility of casual examinations could not be too strongly impressed upon those responsible for our water-supplies.

Professor R. T. HEWLETT (London) pointed out that the chemists had arrived at a more or less uniform procedure and half a dozen chemists examining the same water would probably all adopt the same method and would obtain the same figures. He thought that some scheme might be formulated to obtain uniformity among bacteriologists and advocated the formation of a committee to consider the question. For the bacillus enteritidis sporogenes he did not think inoculation desirable as there were non-virulent varieties.

Professor R. W. BOYCE (Liverpool) thought that the chemists had stood still because they were content with their methods. He was doubtful of the value of bacillus enteritidis sporogenes or other sporing forms in the bacteriological examination of water.

Dr. GLYNN (Liverpool) agreed with Professor Hewlett that there were non-virulent forms of the bacillus enteritidis sporogenes.

Dr. EASTES then moved—

> That a committee of bacteriologists be appointed to consider the question and report to the next Congress.

This was carried unanimously.

The Nature of the so-called Pseudo-Diphtheria (Hofmann) Bacillus and its Significance (if any) in the Bacteriological Examination for Diphtheria.

A discussion on this subject was opened by Dr. LOUIS COBBETT (Cambridge) who concluded that the bacillus of Hofmann differed fundamentally from the diphtheria bacillus in producing no acid out of glucose. It was very widely distributed and was no commoner in "contacts" with diphtheria than in persons from healthy districts. Even when the bacillus was taken from convalescent patients it never had any virulence for the guinea-pig. It was not agglutinated by a serum which agglutinated the diphtheria bacillus and the non-virulent diphtheria bacillus. It formed neither toxins nor toxoids. The published instances were too few to prove the conversion of Hofmann's bacillus into the diphtheria bacillus and *vice versâ*. There were no sufficient reasons for concluding that the bacillus of Hofmann had any relation whatever to diphtheria or to the diphtheria bacillus. The diphtheria bacillus in all probability, when attenuated, became converted, not into Hofmann's bacillus, but into what was now generally called the non-virulent diphtheria bacillus, retaining its power of forming acids out of suitable sugars.

Mr. TANNER, after detailing the characters of the Hofmann bacillus, said that he had been impressed by the frequency with which this organism was met with in throat swabs, how it only might be found at first, was then succeeded by the Klebs-Löffler bacillus and this again was replaced by the Hofmann bacillus during convalescence. He had met with many cases with throat symptoms which had yielded the Hofmann bacillus; should such cases be considered infectious and should they be isolated? In Bournemouth the practice was to regard such cases as infectious *pro tem.* and to examine them repeatedly; if they were sent to the infectious hospital they were placed in isolation wards and not in the diphtheria ward unless Klebs-Löffler bacilli were found. As the result of his experience he could not help thinking that the Klebs-Löffler and Hofmann bacilli were in some way related and he gave several histories of cases in support of this view.

Mr. J. O. HEAVEN (deputy medical officer of health of Bristol) as the result of several thousand examinations considered that the Hofmann bacillus could cause disease which might resemble diphtheria closely, even to fatality. He had had 25 children yielding only the Hofmann bacillus treated in the ordinary wards with cases of diphtheria and not one had contracted diphtheria. In conclusion, he submitted that "Hofmann and pseudo-contacts" should be treated, should be placed under a reasonable amount of restraint, and certainly should be excluded from school attendance.

Mr. E. C. BOUSFIELD (Camberwell) said that it was his invariable practice to return as diphtheritic all cases in which a "diphtheroid" bacillus was found, and no proof had yet been offered in his opinion that the Hofmann bacillus was not a variety of the Klebs-Löffler bacillus, and he pointed to the great variation occurring with other organisms, e.g., bacillus coli and bacillus enteritidis (Gärtner).

Professor STANLEY KENT (Bristol) gave the histories of two cases which had been under his observation. One had a typical attack of diphtheria which ran a mild course, was benefited by antitoxin, and was followed by palatal paralysis. Repeated examinations of the throat and nose showed Hofmann bacilli only in pure culture; the Klebs-Löffler bacillus was never found. The other case had a severe attack of diphtheria which ended fatally. Again, the Hofmann bacillus only, and not the Klebs-Löffler bacillus, was found on repeated examinations. He said that he had little doubt that the Hofmann bacillus was capable of producing symptoms of diphtheria and of spreading the disease.

Dr. BUCHANAN (Glasgow) was surprised that Dr. Cobbett absolutely distinguished between the two bacilli, the Hofmann and the Klebs-Löffler; in his opinion there were a series of transitional forms connecting the two. During the course of the illness there was a universal tendency to a change of type towards the Hofmann bacillus. He did not think that it would be possible to exclude all children with Hofmann bacilli from school, but they should certainly be excluded if they complained of throat symptoms.

Dr. W. A. BOND (London) and Dr. LOW (London) insisted upon the early use of antitoxin if there were any exudation.

Professor HEWLETT said that he was one of those who held that the Hofmann bacillus was a modified Klebs-Löffler bacillus, but he was quite ready to change his opinion should clear proof be furnished that this view was wrong. This he did not think had yet been done. He then drew attention to several points of similarity between the two organisms and said that his view of their relationship was that the Hofmann bacillus was far removed from virulence—i.e., very non-virulent, if such an expression could be used.

Some Observations upon the Bacteria of the Water of Public Swimming Baths.

Dr. GLYNN and Dr. MATTHEWS (Liverpool) communicated a paper upon this subject of important and public interest. They found that the first-class baths contained less bacteria than the second-class and that the number of bacteria rose as bathing went on throughout the day. They estimated that a first-class bather introduced 4,000,000,000 and a second-class bather 6,000,000,000 microbes into the water. Fully-dressed persons walking along the edge of the bath were also responsible for a serious bacterial pollution through the dirt on their boots.

Professor MOORE (Liverpool) read a paper upon

A Chemical Theory of the Propagation and Development of Certain Infectious Diseases,

in which he suggested that in certain instances where no microbes had been detected a chemical agent similar to an enzyme might be the cause. To account for the reproduction of this "catalyser" he pointed out an analogy in certain chemical reactions and suggested that not only did this catalyser cause the symptoms of the disease but at the same time induced certain cells to produce more of itself, so that fresh infection of other individuals became possible.

The theory was criticised by Sir MICHAEL FOSTER (Cambridge), Dr. COPEMAN, Dr. A. S. F. GRUNBAUM (Liverpool), Professor HEWLETT, and Dr. NASH.

The Germicidal Action of Alum upon the Typhoid Bacillus.

Dr. H. S. WILLSON (London) communicated some experiments which he had made in this direction. In distilled water 1 per cent. of alum had little or no effect. In ordinary water or turbid river water alum had a remarkable clarifying effect and produced an enormous diminution in the number of water bacteria in an amount of 35 grains to the gallon. Upon typhoid bacilli being added to the water, however, the alum again had little or no effect.

Dr. DEAN and Dr. TODD (London) communicated a paper upon

The Susceptibility of the Pig to Human Tuberculosis.

In the six experiments which they had made the animals were all infected with the human bacillus, the infection being at least as severe as that described by Professor Koch as the result of the inoculation of the pig with the bovine bacillus.

Dr. H. E. ANNETT (Liverpool) read a paper upon

Tuberculous Expectoration in Public Thoroughfares,

in which he drew attention to the dissemination of tubercle bacilli by the filthy habit of spitting. He had found that tuberculous sputum exposed to sunlight remained virulent up to 24 hours but not for 48 hours. Of 105 specimens of expectoration collected from the streets five contained virulent

Infection of Bovines with Human Tuberculosis.

Professor YOUNG, F.R.C.V.S. (Aberdeen), described some experiments performed by Professor Hamilton and himself upon 20 calves which left no doubt that the human tubercle bacillus could be inoculated upon bovines. He had no doubt that bovine tuberculosis could be transmitted to man and that the milk was the most potent factor in this transmission.

Milk-supply of Large Towns.

Mr. LLOYD, M.R.C.V.S. (Sheffield), drew attention to the objectionable manner in which the cows and milk were kept and treated, to the sources of contamination, to the effects of food and the operation of milking upon the quality of the milk, to adulteration, and to the measures to be taken to protect the milk-supply. The two foregoing papers were followed by an interesting discussion.

The Influence of Surroundings and Locality upon the Recurrence of Malignant Disease.

Mr. D'ARCY POWER (London) invited opinions upon this question and asked whether, after an operation for malignant disease, it was advisable or inadvisable to send a patient back to his old house and former surroundings. Some striking instances were quoted in which recurrence took place when patients were sent back to their old surroundings and did not do so when a complete change in former habits, &c., was made. The paper was published in full in THE LANCET of July 25th, p. 221.

Papers were also read by the following: Dr. A. C. COLES (Bournemouth) upon the Resistance of Acid-fast Bacilli to Decolourising Agents; Dr. R. LORD (London) upon Acetozone, a New Germicide; Dr. J. W. W. STEPHENS (Liverpool) upon Staining Bacterial Flagella with Silver; Mr. K. WELLDON GOADBY (London) upon a Card Index for Bacteriological Work; Dr. COPEMAN upon an Outbreak of Cow-pox; and Mr. STAFFORD JACKSON upon Diseases of Animals Communicable to Man.

IV.—SECTION OF TROPICAL SANITATION.

Dr. A. NELL read a paper on

Hygiene in West African Mining Camps.

He emphasised those elementary methods of promoting individual and general hygiene so well understood in India and Ceylon but which up to the present had been completely neglected in Africa. He pointed out how apparently trifling details made the difference between a healthy and an unhealthy station.

The Prevention of Malaria on Shipboard.

Mr. EVANS of the Elder-Dempster Line said that so long as the taking of quinine was a voluntary matter, so long would malaria remain on shipboard. It would be wise to have a Board of Trade regulation to insist upon a regular "quinine parade." Officers and men should be educated as to the value of quinine and as to the mosquito theory. It would be difficult to exclude mosquitoes altogether from ships, hence the value of quinine.

Dr. C. CHRISTY (Liverpool) discussed the measures to be directed against the mosquito and the value of the system of the segregation of Europeans and exclusion of natives. The last he described as being the only measure which afforded the traveller any real hope of safety.

Other communications were made by Dr. MCCULLOCH upon Proper Medical Supervision upon Indian Railways and by Mr. J. CANTLIE (London) upon the Dissemination of Plague by Animal Food.

V.—SECTION OF MUNICIPAL HYGIENE AND SANITARY LEGISLATION.

Sanatoriums for Tuberculosis.

A discussion upon the Provision of Sanatoriums for Consumptives was opened by Professor W. R. SMITH (London) who saw great difficulty in compulsory notification, the isolation of consumptives, and the provision of adequate accommodation for tuberculous patients.

Mr. MAXWELL LAWFORD (London) read a paper upon

The Application of Pneumatic Power to Works of Municipal Hygiene,

and discussed the growing tendency to make use of pneumatic power in connexion with water-supply and sewerage.

Mr. MORESBY WHITE discussed

Recent Sanitary Legislation,

and dealt with the necessity for the simplification of legislation and of the various legal powers of sanitary authorities. *"Open Spaces" and "Garden Cities" were the titles of* other communications.

VI.—ENGINEERING SECTION.

Professor HELE SHAW (Liverpool) presided over this section and in an interesting address dealt with the subject of road traction and with the importance of increasing the speed of road vehicles.

Professor BOYCE read a short paper on

Sewage Effluents and the Construction of Filter-beds.

He advocated the bacteriological treatment of sewage and explained the system adopted by the Liverpool corporation. In the course of subsequent discussion the system commended by Professor Boyce and that of precipitation were considered.

VII.—SECTION OF CHILD STUDY AND SCHOOL HEALTH.

Professor C. S. SHERRINGTON (Liverpool) presided over this section.

Child Study.

Mr. H. HOLMAN, H.M.I., of Bury opened a short discussion on the subject of Child Study: its Scope and Method in Education. He contended that the majority of parents made a great and cardinal mistake in treating a child as a man in miniature. A child was only so inasmuch as he went through stages of progress in new knowledge which were repeated in adults who attacked any new form of study. True child study needed very high qualifications and from a medical point of view an infant needed vastly different treatment from a grown person. He urged upon all school teachers the great necessity of attaining a definite knowledge of the science concerning the human being and of making themselves familiar with both the physiology and psychology of child life. Hitherto great danger had arisen through the medical man dictating to the educationist and the educationist in turn dictating to the medical man.

A brisk discussion arose on the question of the introduction of military drill into schools which, on physical grounds, was strongly advocated by Captain J. C. ROBERTSON who urged that systematic physical training should be an integral part of education in all schools under public authority and maintained that of the various methods of physical culture military drill had been proved by experience to be the simplest and the best.

VIII.—SECTION OF PORT SANITARY ADMINISTRATION.

Alderman D. CLARKE (Liverpool) in his presidential address referred to the work done by the port sanitary authority of Liverpool, especially in regard to the checking and preventing of the introduction of sea-borne infectious disease.

Inspection of Food at the Port of London.

Dr. HERBERT WILLIAMS (London) read a paper on this subject. Looking at the large proportion of food which was rapidly perishable, careful inspection, he said, was of first importance and there should be ample powers for seizure, condemnation, and destruction.

Dr. PRINGLE followed with a Plea for Community of Action among Port Sanitary Authorities, Alderman S COHEN (Hull) with a paper on the Port Sanitary Authority and its Relation to Emigrants, and Mr. R. SHERITON HOLMES (River Tyne) on the Question of the Payment of Delegates' Expenses.

IX —LADIES COMMITTEE AND SECTION OF DOMESTIC SANITATION.

Elementary School Hygiene, by Mrs. BULNOIS; Anti-Faddism, by Miss A H. A. BOYLE, M.D. (Brighton); Sterilised Milk, by Miss HEALD; and the Care and Feeding of Infants, by Miss KATE MARION HUNTER, L.S.A. (London), were some of the subjects discussed in this section.

SANITATION IN WEST AFRICA.

At the termination of the proceedings of the Congress of the Royal Institute of Public Health at Liverpool on July 21st an important conference of West African merchants and others was held at the Exchange Station Hotel. The conference was preceded by a luncheon given by Sir Alfred Jones, K.C.M.G., who, however, was unable to preside, and in his absence the chair was occupied by Mr. H. Cotterell, chairman of the African Association. After explanatory speeches by the chairman, Major Ronald Ross, and Mr. John Holt, the following motions were agreed to unanimously:—

1. That a fully qualified medical officer of health with an adequate sanitary staff should be appointed to each of the principal West African towns whose sole duty it shall be to attend to sanitary matters in those towns.

2. That there should also be appointed for all the West African colonies an expert sanitary commissioner, on the Indian model of sanitary organisation, the duties of the said commissioner being as follows: (*a*) To spend at least half the year in visiting as many parts of the said colonies as possible for the purpose of inspecting and reporting upon the state and progress of sanitation in them, such report being made direct to the Colonial Office as well as to the Government of each colony; (*b*) to supervise the sanitary statistics and to advise the Colonial Office regarding sanitary measures of importance.

3. That the Colonial Office be asked to publish annually a sanitary report containing reliable statistics of the sickness and mortality, especially among Europeans, in the said colonies, and also giving details of the sanitary work done in them, such report to be of the nature of the annual report published by the Sanitary Commissioner of the Government of India, and that a copy of these resolutions be sent to Mr. Chamberlain.

Looking Back.

FROM

THE LANCET, *SATURDAY*, JULY 30, 18[illegible]

THE ancient physicians, it would appear from CELSUS,* knew but little of operative midwifery, and were consulted for the most part, only, when the loss of the child was certain, and the recovery of the parent doubtful; and as such cases probably occurred but seldom, the imperfection of their knowledge is not to be wondered at, since they necessarily wanted experience, and the *tact* acquired by practice, by which alone the art could have been well understood, successfully practised, or materially improved. During the dark ages which succeeded to the downfall of the Roman empire but little was done towards the improvement of midwifery; and until the middle of the seventeenth century, when male practitioners of the obstetric art first came into vogue in ordinary cases, no decided addition had probably been made to the knowledge of the ancients—"It is pretty generally known," says Dr. Davis, "that the Duchess de la Viliere, a favourite mistress of Louis the Fourteenth of France, was the first female who was induced to place herself under the exclusive obstetric care of a professor of surgery, independent of any anticipated necessity for a surgical operation. That event took place in December, 1663; and Julian Clement, the fortunate attendant upon the case, was soon after appointed to the new and lucrative office of Midwifer to the Princesses of France." Clement advanced the practice of midwifery, but introduced no improvements into the instrumental part of the art; nor "were any accessions of this kind made to it for near half a century after his time." Improvements, however, beginning to multiply, a prodigious clamour was raised by the female practitioners, who accused the surgeons (and probably with justice) of an undue attachment to the use of instruments; indeed the clamour to the present day has not wholly subsided. The forceps and vectis, being employed unnecessarily, were afterwards disregarded where they were indicated, like some of the contrivances and remedies of our own day, which, being overrated at first, are sooner or later entirely abandoned. No doubt labour is a natural and not a morbid process—that the resources of unassisted nature are generally sufficient, and that the interference of art (in ninety-nine cases of a hundred) is at best but auxiliary and trifling; still as anomalous cases, and cases of difficulty and danger, may and do occur, it is certainly incumbent on those who may practise this branch of the profession, to capacitate themselves for acting with promptitude in every case to which they may be called, without trusting to the chances (which undoubtedly are much in their favour) of having little to do. Thus, although a fatal issue may not always be inevitable, yet it will seldom occur, and if it do, a consciousness of having done the utmost for the patient will be the best and only solid satisfaction the practitioner can have.[1]

---

* Lib. vii. Cap. xxix. This author speaks only "of the method of extracting a *dead* fœtus," and apparently knew no instrument but the crochet. HIPPOCRATES and GALEN were equally uninformed.

[1] Excerpt from Review of *Elements of Operative Midwifery* by DAVID D. DAVIS, M.D., Member of the Royal Colleges of Physicians of London and Edinburgh and Lecturer on Midwifery. London, 182 Hurst, Robinson, and Co. and S. Highley.

MEDICINE AND THE LAW.

Anthrax and Accident.

IN a case under the Workmen's Compensation Act at Kidderminster the county court judge has held that anthrax infection is an "accident" within the meaning of the Act and that the widow of a workman who died from anthrax acquired when sorting Persian wool for his employers is consequently entitled to compensation at their hands. The matter is of considerable interest to workmen and employers and probably the Court of Appeal will be called upon for a final decision upon it. The section of the Act gives to the workman compensation for "personal injury by accident arising out of, and in the course of, his employment." It has been held that whether the injury is due to an "accident" or not is a question of mixed fact and law and consequently the Court of Appeal will review the finding of a county court judge on the subject, although it may not be willing to disturb it. In a recorded case an "accident" has been spoken of as something "fortuitous or unforeseen," and it has also been said that "in its ordinary sense the word accident necessarily involves casualty, violence, or *vis major.*" In the case mentioned it was decided that a woman who sustained internal injury through lifting a succession of heavy boxes was not injured by an "accident." The county court judge at Kidderminster held that some force caused the anthrax bacilli from the wool to float in the air and to impinge on the deceased and that this circumstance constituted the infection an "accident."

Houses overlooking Open Spaces.

Under the Metropolitan Open Spaces Acts and under the Disused Burial Grounds Act areas of considerable extent have been thrown open for the public benefit in many parts of the metropolis. They are of use as recreation grounds, where the neighbouring inhabitants and their children can obtain a little fresh air and sometimes look upon green grass and trees, while the houses adjoining and overlooking them enjoy the obvious advantage derivable from facing an open space. The Paddington borough council, however, anxious lest some houses built so as to overlook a large disused graveyard should acquire a prescriptive right to enjoy light and air uninterrupted, erected a hoarding upon the land under its control and an action was brought by those interested in the houses in order to test the council's right to do this. Mr. Justice Buckley's decision was in the council's favour, but the Court of Appeal, consisting of Lord Justice Vaughan Williams, Lord Justice Romer, and Lord Justice Cozens-Hardy, has now taken a different view and the hoarding will have to be removed. As far as we understand, the open spaces made public where there have been burial grounds are intended to remain open spaces for ever; no one may build upon them except where a church has to be enlarged and the borough of Paddington having no power in any case to build on the land in question will not be in any worse position owing to the decision of the Appeal Court. The benefit derivable by a locality from an open space is not confined to the pleasure and recreation of those who resort to it. The houses immediately adjoining it gain considerably and others near it do so to a less degree. It would diminish the utility of such open spaces considerably if unsightly erections were permitted upon them in order to guard rights which no one would ever wish to see exercised. The appeal in the case referred to (Boyce *v.* the Paddington Borough Council, July 25th, 1903) involved not only legal questions of some intricacy but a matter of considerable public importance and no one should regret the decision at which the court arrived.

THE NEW BUILDINGS OF CAMBERWELL INFIRMARY.

THE board of guardians of the parish of St. Giles, Camberwell, S.E., after three years' building operations and at a gross cost of close upon £200,000, opened on July 24th very extensive new infirmary buildings for South London. The old and comparatively small building, which was erected in 1873, has been altered and modernised so as to form part of the institution, which the board wish to be known as Camberwell Infirmary and which, although technically a parish infirmary, must from its position and extent be regarded as really a general hospital, capable of dealing with a large number of accident and acute cases of all kinds. The institution is in Brunswick-square—a well-wooded open space recently acquired for the public, quite near to Camberwell Green and the main highway therefrom to Peckham and New Cross, but sufficiently far away to be out of the noise of the street traffic. It consists of 21 buildings standing on a site of several acres, practically surrounded by roads, all the buildings being connected by glass-covered ways and subways. It will provide accommodation for 800 patients, have a resident staff of five medical men, and officials, nurses, and servants to the number of about 160, with Mr. W. J. O. Keats at their head as medical superintendent. The various erections are built of fire-resisting material and special provision is made for escape in case of an outbreak of fire. The institution contains a fully-equipped operating theatre with recovery-room attached and an electric treatment-room with all modern appliances—"x" rays, galvanic and faradic electrical baths, and all the usual appliances for dealing with diseases of the nervous system. On each of the four floors of three pavilions there is a ward of 24 beds, with windows on three sides, and other wards of six, four, and two beds respectively—so arranged, of course, as to afford opportunity for classification. On every floor a balcony the whole length of the large ward faces west and is sheltered from all cold and side winds. The large ward of the top floor has been specially designed for consumptive patients and practically the whole of the inclosures on three sides consist of opening windows for open-air treatment, there being above a flat roof on which patients may spend all the day with something of interest to see in the panorama stretching for miles across London. This arrangement for consumptive patients is new in the metropolis and so far as is known not yet introduced in any of the general hospitals of the large towns throughout the country. Special attention has been paid to the provision and furnishing of a children's pavilion. The whole institution is electrically lighted; it has electric lifts of a special labour-saving type which are capable of hoisting and lowering beds of full length; it has laundry motors, electric ventilation, and a heating system of a kind believed to exist in only one other institution in London—open fires being allowed for in the sitting-rooms only. The administrative offices are in the centre and so is the nurses' home, in which there are several large rooms for dining, writing, recreation, &c., and to which a pleasant garden is attached.

At the formal opening the architect—Mr. EDWIN T. HALL, F.R.I.B.A., F.S.I.—handed to Mr. Alfred Foster, chairman of the board of guardians, who presided, a key with which to unlock the main door of the administrative building of, he said, this new temple of Hygeia. Mr. FOSTER, in declaring the building open, mentioned that the guardians would get from the Local Government Board £53 000 as its share of the money realised by the sale of what were known as the Sutton Schools. The population of the parish, he stated, had risen from 111,302 in 1873, to 259,339 in 1903, the indoor adults under its charge from 506 to 2167, and the children from 421 to 1028. Mr. WILLIAM T. PARTRIDGE, chairman of the infirmary committee during the last nine or ten years, congratulated the large number of Camberwell ratepayers who had come to take part in the opening ceremony on having secured for their great parish an infirmary capable of doing the work that was to be done. Hitherto they had been much handicapped, but that state of matters was now at an end, and as they were such a long distance from the general hospitals of South London—St. Thomas's and Guy's—they would be able with their accommodation to receive a greater number of acute medical and surgical cases than was usually undertaken by metropolitan infirmaries. 14 years ago they had not a single trained nurse, but of the 64 employed at present—a number to be gradually raised to 116—there was not one who had not passed through the training school. Dr. J. T. MACNAMARA, M.P. for North Camberwell, felicitated everyone concerned on the completion of the buildings. He did not think the money they cost could be better spent, but he thought that the Local Government Board ought to give a very generous contribution towards the cost for the reason that so many people from other districts of London and from the country came into the parish and while getting the [illegible] burdens which the more [illegible] upon to bear. To the poor [illegible] that this large extension of the Camberwell Infirmary must prove an unspeakable boon.

On the motion of the Mayor of Camberwell (Mr. GODDARD CLARKE, J.P., L.C.C.) a vote of thanks was accorded to the chairman, and then Mr. Hall and the stewards led the visitors, in parties of 50, to inspect the buildings.

ASYLUM REPORTS.

County and City of Worcester Asylum (*Annual Report for 1902*).—The average number of patients resident during the year was 1189, comprising 524 males and 665 females. The admissions during the year amounted to 268—viz., 114 males and 152 females. Of these 228 were first admissions. Mr.

G. M. P. Braine-Hartnell, the medical superintendent, states in his report that the ratio of insane patients per 1000 of population in the geographical county of Worcester was 2·87 in 1901, as compared with a ratio of 1·88 in the year 1861. Further inquiries made by Mr. Braine-Hartnell show "that the insane community of Worcestershire during the 40 years (1861–1901) has increased by 481 *beyond or in excess* of the number we should expect, having regard to the natural increase of population." Of the patients admitted during the year only 23 were in good bodily condition, the rest (243 in number) being in indifferent or bad health. The number of patients discharged as recovered during the year amounted to 96—viz., 39 males and 57 females, or 8·1 per cent. of the average number resident. The deaths during the year amounted to 116, or 9·7 per cent. as calculated on the same basis. Of the deaths four were due to renal disease, six to epilepsy, nine each to cardiac disease and pneumonia, 11 to general paralysis of the insane, 16 to colitis, 19 each to senile decay and general paralysis, and the rest to other causes. Post-mortem examinations were made in 94 cases. A married female patient was confined a fortnight after admission. "She still remains," adds Mr. Braine-Hartnell, "a patient." Four patients escaped during the year and all but one were recaptured within a short time. A few cases of measles and typhoid fever occurred in the asylum, affecting both patients and attendants. "Influenza has been rife among the staff and some of the patients have suffered." An outbreak of colitis affected 25 male and 46 female patients. Owing to the prevalence of small-pox in the county the patients and staff were vaccinated. The results were good, as small-pox did not break out in the institution. The average weekly cost of maintenance per patient has been raised from 7*s.* 7*d.* to 8*s.* 2*d.* The Commissioners in Lunacy state in their report that the asylum is overcrowded and that further accommodation is needed, that the wards were bright, cheerful, and comfortable, that the dormitories and bedding were in excellent condition, and that the medical case-books were very well kept. The committee of management states in its report that owing to overcrowding of the asylum it has made contracts with the authorities of Derby and Northampton county asylums to board out 45 patients.

Royal Edinburgh Asylum for the Insane (*Annual Report for 1902*).—The average number of patients resident during the year was 946, comprising 471 males and 475 females. The admissions during the year amounted to 423—viz., 189 males and 234 females. Of these, 329 were first admissions. Dr. T. S. Clouston, the medical superintendent, states in his report that in no less than 119 cases, or 28 per cent. of the admissions, the mental breakdown was attributable to alcoholic intemperance. "This is the highest number that we have ever had sent here as the result of alcoholic excess. It is most sad and discouraging that this preventable cause of the most terrible of all human diseases should thus contrive to increase. It is a veritable plague-spot in our social life." The mean age of those admitted steadily increases, having gone up from 40 years in 1901 to 43·3 years in 1902. No fewer than 56 of the admissions, or 13 per cent., were cases of general paralysis. "This is, with the exception of last year, the largest number of [cases of] this disease we have ever had sent to us, and confirms my remarks in last year's report as to the distinct increase of this deadly disease in this district at least. From having stood low, in regard to this disease 30 years ago, our admission rate is now the highest in Scotland. It, too, like alcoholic insanity must be regarded as a largely preventable scourge of humanity." In addition to these 56 cases of general paralysis, there were 80 patients who suffered from advanced senility and gross brain disease, thus showing that one-third of the admissions were incurable in character from the beginning. The number of patients discharged as recovered during the year amounted to 134, or 14·1 per cent. of the average number resident. The deaths during the year amounted to 138, or 14·5 per cent. as calculated on the same basis. Of the deaths three were due to epilepsy, nine to pneumonia, 16 to pulmonary tuberculosis, 17 to cardiac disease, 19 to senile decay, 42 to general paralysis of the insane, and the rest to other causes. Post-mortem examinations were made in 103 cases. "The most alarming event of the year was an outbreak of asylum dysentery or colitis. ...... We had 27 female cases. ...... I may say that of the whole 27 cases only three could be said to be in anything like fair bodily health and condition before they were attacked by the disease. Seven of the 27 patients died. ...... The epidemic was treated from the beginning by the strictest isolation and disinfection." One possible means of the propagation of the disease was the cats of the ward, two of which were found to be suffering from it. The cats in the establishment were killed on this discovery being made. "My general conclusions in regard to this unfortunate epidemic," adds Dr. Clouston, "are that it was predisposed to by the overcrowded state of the wards, particularly our hospital, the patients being weak and specially susceptible to any disease, that the actual disease was introduced somehow from defective sanitary arrangements, and that, to a certain extent, it was propagated in the house by direct infection." The Commissioners in Lunacy state in their report that "the proportion of deaths [from general paralysis] greatly exceeds the average of the other Scottish asylums and judging from the number of cases suffering from the disease in the wards of the asylum, there is reason to believe that this deadly affection has attained an unprecedented prevalence in the city of Edinburgh." They also state that the condition of the patients was tidy and indicated careful attention on the part of the attendants and nurses, that the dietary was varied and sufficient, that the wards were scrupulously clean, that the sitting-rooms and bedrooms were brightly decorated and well furnished, that the patients had ample opportunities for exercise and recreation, and that the medical case-books and records were found to be carefully and regularly kept. The committee of management states in its report that pending the erection of the Bangour Asylum the district board has arranged to erect temporary accommodation for 150 patients which will, it is expected, be ready for their reception in the course of a few months and will to that extent relieve the overcrowding at the asylum. The cost of maintenance of pauper patients per head has fallen from £33 2*s.* 4*d.* in 1901 to £31 15*s.* 8½*d.* in 1902, being a decrease of £1 6*s.* 7½*d.*

Joint Counties Asylum, Carmarthen (*Annual Report for 1902.*)—The average number of patients resident during the year was 646, comprising 330 males and 316 females. The admissions during the year amounted to 122—viz., 66 males and 56 females. Of these 109 were first admissions. Dr. E. Goodall, the medical superintendent, states in his report that the average age on admission was 40 years for males and 39 years for females. A hereditary tendency to insanity was traceable in 42 per cent. of the admissions, alcoholic intemperance was met with in 15·2 per cent., and senile decay was the cause of insanity in 14 per cent. Of the admissions 37 were more or less actively suicidal and 26 were subject to dangerous impulses. The number of patients discharged as recovered during the year amounted to 32—viz., 20 males and 12 females, or 4·9 per cent. of the average number resident. The deaths during the year amounted to 63—viz., 33 males and 30 females, or 9·8 per cent. as calculated on the same basis. Of the deaths three each were due to epilepsy and senile decay, four to renal disease, seven each to broncho-pneumonia and general paralysis, eight to cardiac disease, 17 to pulmonary and other forms of tuberculosis, and the rest to other causes. Post-mortem examinations were held in 56 out of the 63 deaths. The general health of the institution has been satisfactory throughout the year apart from the undue proportion of cases of pulmonary tuberculosis. "The segregation of cases of consumption is highly desirable, otherwise they act as foci of contagion. There is at present no suitable building available here" for such cases. The average weekly cost of maintenance is between 8*s.* 5*d.* and 8*s.* 9*d.* per patient. "In addition to the more usual means," says Dr. Goodall, "we continue to use the electric bath [in the treatment of patients]. It appears to be the best method of applying the electric current for general purposes and shows itself to be a valuable aid to treatment in certain cases." The Commissioners in Lunacy state in their report that the condition of the patients was satisfactory in matters of dress and personal tidiness, that their behaviour was orderly, and that the medical case-books were very well kept. They recommend that an improved should dietary be adopted for the more poorly nourished patients. They state that the wards and dormitories generally were in a satisfactory condition, that the former were bright and cheerful, and that the latter were sweet and clean. The committee of management states in its report that the new hospital for infectious diseases is being built, but that progress is necessarily slow as asylum labour only is used. The committee has under consideration the adoption of a scheme for pensioning servants who have been in the asylum service for long periods and who are through age incapacitated from fulfilling their duties.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8687 births and 3874 eaths were registered during the week ending July 25th. he annual rate of mortality in these towns, which had een 14·4, 13·7, and 13·5 per 1000 in the three preceding 'eeks, further declined to 13·4 per 1000 last week. In ondon the death-rate was 12·7 per 1000, while it averged 13·7 in the 75 other large towns. The lowest deathates in these towns were 5·7 in Tottenham, 6·3 in Reading nd in Handsworth, 6·9 in Walthamstow, 7·0 in Northmpton, 7·1 in East Ham, 7·2 in York, and 7·3 in Hornsey; ie highest rates were 18·0 in Liverpool, 18·2 in Ipswich, 8·9 in Warrington and in Burnley, 19·1 in Stockport nd in St. Helens, 19·2 in Bolton, and 20·6 in Bury. he 3874 deaths in these towns last week included 31 which were referred to the principal infectious iseases, against 436, 441, and 473 in the three receding weeks; of these 531 deaths 225 resulted om diarrhœa, 111 from measles, 74 from whoopingough, 49 from diphtheria, 40 from scarlet fever, 27 om "fever" (principally enteric), and five from smallox. No death from any of these diseases was registered ist week in Hornsey, Tottenham, Hastings, Bournemouth, outhampton, Reading, Devonport, Burton-on-Trent, Handsorth, King's Norton, Derby, or Stockton-on-Tees; the ighest death-rates from the principal infectious diseases ere recorded in Stockport, Birkenhead, Bootle, Warringon, Burnley, Leeds, Sheffield, Tynemouth, and Rhondda. he greatest proportional mortality from measles occurred n *Ipswich, Aston Manor, Stockport, and Sheffield; from* hooping-cough in Willesden; from "fever" in Bootle; and rom diarrhœa in Birkenhead, Bootle, Warrington, Bury, ateshead, and Tynemouth. The mortality from scarlet fever nd from diphtheria showed no marked excess in any of the arge towns. Small-pox caused one death in Smethwick, ne in Liverpool, one in Leeds, one in Hull, and one in Newcastle-on-Tyne, but not one in any other of the 6 large towns. The Metropolitan Asylums hospitals conained 71 small-pox patients on Saturday last, July 25th, gainst 57, 77, and 71 on the three preceding Saturdays; 12 ew cases we , against four, 31, nd seven in The number of carlet fever hese hospitals and n the London Fever Hospital, which had been 1646, 1700, nd 1710 at the end of the three preceding weeks, had urther increased to 1711 at the end of last week; 229 ew cases were admitted during the week, against 241, 53, and 243 in the three preceding weeks. The deaths eferred to diseases of the respiratory organs in London, which had been 164, 127, and 115, in the three preceding weeks, rose again last week to 130, but were 26 below the number in the corresponding period of last ear. The causes of 41, or 1·1 per cent., of the deaths n the 76 large towns last week were not certified either by registered medical practitioner or by a coroner. All the auses of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Bradford, Leeds, and in 48 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, St. Helen's, Blackburn, Sheffield, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·3, 16·2, and 15 2 per 1000 in the three preceding weeks, rose again to 15 4 per 1000 during the week ending July 25th and was 2 0 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·1 in Leith and 12·0 in Greenock to 16·9 in Glasgow and 19·5 in Paisley. The 503 deaths in these towns included 34 which were referred to diarrhœa, 11 to whooping-cough, seven to measles, six to "fever," and four to scarlet fever, but not one to either small-pox or diphtheria. In all, 62 deaths resulted from these principal *infectious diseases last week, against* 59, 82, and 57 in the three preceding weeks. These 62 deaths were equal to an annual rate of 1·9 per 1000, which was 0 1 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 17, 31, and 22 in the three preceding weeks, rose again last week to 34, of which 11 occurred in Glasgow, nine in Edinburgh, five in Dundee, three in Paisley, two in Aberdeen, and two in Greenock. The deaths from whooping-cough, which had been 18, 18, and 15 in the three preceding weeks, further declined to 11 last week and included six in Glasgow and four in Edinburgh. The fatal cases of measles, which had been 13 and 11 in the two preceding weeks, further decreased last week to seven, of which four were registered in Glasgow and two in Paisley. The deaths referred to different forms of "fever," which had been six, nine, and three in the three preceding weeks, rose again to six last week and included three in Glasgow and two in Edinburgh. Of the four fatal cases of scarlet fever three occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 86, 90, and 73 in the three preceding weeks, rose again last week to 79, but were slightly below the number in the corresponding period of last year. The causes of 14, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 17·2, 18·0, and 16·0, per 1000 in the three preceding weeks, rose again to 17·5 per 1000 during the week ending July 25th. During the past four weeks the death-rate has averaged 17·2 per 1000, the rat London and 15 2 belonging to Dubl showed an excess of 11 over the number in the preceding week and included nine which were referred to the principal infectious diseases, against five, two, and six in the three preceding weeks; of these, three resulted from whooping-cough, two from small-pox, and one each from measles, scarlet fever, "fever," and diarrhœa, but not one from diphtheria. These nine deaths were equal to an annual rate of 1·2 per 1000, the death-rates from the principal infectious diseases last week being 1·4 in London and 2·7 in Edinburgh. The fatal cases of whooping-cough, which had been one in each of the two preceding weeks, rose last week to three. Two deaths from small-pox were registered, against one in the preceding week. The 127 deaths in Dublin last week included 13 of children under one year of age and 37 of persons aged 60 years and upwards; the deaths of infants showed a decline of 11, and those of elderly persons an excess of eight, as compared with the respective numbers recorded in the preceding week. Four inquest cases and five deaths from violence were registered and 47, or more than a third, of the deaths occurred in public institutions. The causes of three, or more than 2 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Samuel Keays has been placed on the retired list of his rank at his own request. Dated July 14th, 1903.

The following appointments have been notified:—Surgeons: H V. Wells to the *Dwarf* and G. F. Alderdice to the *Hogue*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J Armstrong retires on retired pay. Dated July 29th, 1903. Captain R T. Brown is placed on temporary half-pay on account of ill-health. Dated May 13th, 1903.

Lieutenant Crossley and Lieutenant Harding are posted for duty to the Station Hospital, Shorncliffe, and the Station Hospital, Western Heights, Dover, respectively.

VOLUNTEER CORPS.

Rifle: 1st Nottinghamshire (Robin Hood): Surgeon-Lieutenant J. B. Roberts to be Surgeon-Captain. Dated June 27th, 1903. 2nd Volunteer Battalion the Prince of Wales's (North Staffordshire Regiment): Surgeon-Major H. J. Fausset to be Surgeon-Lieutenant-Colonel. Dated July 25th, 1903.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Manchester Companies: George Fyfe Waterson to be Lieutenant. Dated July 25th, 1903.

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY.

5th London: Surgeon-Captain J. G. Fraser, 19th Middlesex Volunteer Rifle Corps, to be Captain and to command under paragraph 55A Volunteer Regulations. Dated July 25th, 1903.

SUNSTROKE: A CALAMITOUS MARCH.

The Vienna correspondent of the *Standard* furnishes some particulars regarding a calamitous occurrence which recently befell some troops engaged in military field operations in Herzegovina. According to the description published in that journal of July 27th it appears that two battalions of the 12th Austro-Hungarian Infantry made a march of some 20 miles and had a sham fight on the way with the garrison of Bilek. This small force suffered so severely from sunstroke that the losses attending these military manœuvres were as serious as in war itself. The mid-day heat was very great, the country mountainous, without shade or water, and the men marched with field service equipment, each man carrying about 50 *pounds. According to reports in the Hungarian papers more* than 400 soldiers fell out and were left lying on the road, while the War Office admits that no fewer than 15 died from sunstroke and that about 40 more were taken, partially unconscious and in a critical condition, to hospital, while another 60 are suffering less seriously from the effects of sunstroke. The matter has naturally caused a good deal of adverse criticism and the conduct of the military authorities will no doubt be made a subject of official inquiry.

THE ARMY AND NATIONAL PHYSIQUE.

This subject continues to occupy attention and its importance is beginning to be fully recognised. It is the alleged physical degeneration of the class which provides the bulk of our soldiers that mainly concerns us, when the unskilled labouring class is no longer content to remain in rural districts but migrates to large towns and only adds to the existing overcrowding and all the other evils to be found in city slums. Although it is undeniable that a system of national training can do much it manifestly cannot do everything. In cases where the conditions have throughout been exceptionally unfavourable—from infancy upwards to early manhood—it is too late to expect that all the results can be effaced by any mere physical training, notwithstanding that it is capable of doing a good deal under other conditions in improving physical development. We require to enlarge our field for recruiting and to tap other sources of supply.

There will be two vacancies this month in the senior rank of the Army Medical Staff as Surgeon-General W. S. M. Price, Principal Medical Officer, Bombay, reaches the limit of age on August 11th, as does Surgeon-General Sir W. D. Wilson, K.C.M.G., attached to the Home District, on August 27th. The *Army and Navy Gazette* understands that one of these vacancies will be utilised to absorb Surgeon-General W. J. Fawcett, who was recently promoted to act as Principal Medical Officer of the 3rd Army Corps in Ireland.

The number of competitors for 30 commissions in the Royal Army Medical Corps at the examination which commenced on July 29th is 72.

"Audi alteram partem."

THE CAVENDISH LECTURE ON DISEASES OF THE ASCENDING AORTA.

To the Editors of THE LANCET.

SIRS,—I have read with the pleasure I always experience in perusing his work, Professor T. Clifford Allbutt's lecture on Diseases of the Ascending Aorta, published in THE LANCET of July 18th. I also had the privilege of hearing the Cavendish lecture delivered. We should be grateful to Professor Allbutt, in the midst of his academic activities for having detached himself from these *to lay before us so* much of interest bearing on his theme and in so happy a manner. For, although the kernel is the meat of the nut, there are those—and I confess myself one of them—who prefer to reach the kernel leisurely with the aid of crackers, artistic in shape if possible, to having the naked contents placed before them in balder fashion. With these remarks I perceive you, Sirs, sympathise in your leading article on the lecture in THE LANCET of July 25th. There are many sound and nutritious nuts in the graceful dish which Professor Allbutt has placed before us, but I have picked up one specially recommended by the lecturer, cracked it leisurely, and laid it aside as not suiting my palate, very possibly owing to some defect in my own taste which I cannot help and can only acknowledge. Perhaps I may in time become less fastidious on this point or even, as is the case with some viands, develop an acquired liking for it. The nut in question has been a very hard one to crack for many a day. There are those, indeed, who affirm with some show of reason that this particular kind of nut has never yet been cracked, often as it has been served up at medical banquets and sometimes with the recommendation that it had been cracked and enjoyed by many notable physiological and medical gourmets. Need I add that the nut in question is that always interesting and still obscure problem concerning the nature and site of angina pectoris. The subject occupies a considerable portion *of Professor Allbutt's remarks on the symptomatology* of the condition of which he treats. It is with him synonymous with aortic pain, arises in some portion of the aorta more or less near its origin, and causes its fatal results when these ensue by overthrowing the heart secondarily. That such is the case at times I should be the last to dispute, but Professor Allbutt so states his position as to leave the impression that the agony which distresses or kills a patient in these circumstances does *not* frequently arise elsewhere. He even utilises Pawinski's work in support of his "long-published opinions on the nature of angina," and these, as I have said, associate the pain chiefly with the aorta. The condition which Pawinski describes might, of course, be argued to be as closely related to the coronary circle as to the aorta, but it has probably little to do with either and must affect mainly the nervous mechanism common in some measure to both these structures and to the parts immediately inflamed. Pain of sufficient severity in or near the heart, or, indeed, remote from it, will, we know, at times inhibit a heart into syncope, especially if, as Professor Allbutt points out, the organ be degenerate in fibre. When, however, he states that the "glamour of great names," the "tenacity of a habit of thought," and the "sapping effect of fixed doctrine upon simplicity of thought," have had such an effect as too exclusively to fix our regard upon the coronary arteries as the site of angina pectoris, I can only agree with him with some reservation. The coronary arteries may indeed have been too frequently regarded as the place of origin of this important syndrome, but they can scarcely be said to have been too minutely examined. Beyond having been split up, or dissected, or casually inspected at their orifices, so far as my acquaintance with the literature of the subject is concerned, they have rarely been examined by microscopic section sufficiently carefully to declare their true condition and we are even now largely ignorant of their nervous anatomy. But, this aside, my object in addressing you, Sirs, on this point has been to express my conviction that the time is past for too exclusively situating the causes of angina pectoris in this or that tissue of the heart or its neighbourhood, whether it be the aorta, the coronary arteries, the cardiac muscle, or the extra-cardiac nervous system. It may arise in any of these situations or in one or more of them, and to determine where and how in any particular case we require much more minute examination to be made in fatal cases of the textures of and around the heart than has hitherto been the case in reports of the condition, and more especially with reference to that most neglected field in cardiac pathology, the investigation of the cardiac nervous system after death. I trust that the remarks I have ventured to make may not be regarded as presumptuous when offered in criticism of the views of one who has done so much to enlist our interest in this important question, but I feel convinced that until we break loose from the warp of single localisation in theories of angina—a mood observed in so pronounced and dogmatic a manner in the published conclusions of, for example, M. Huchard—we shall *long find* this subject a very hard nut to crack and not very digestible even when we flatter ourselves that we have succeeded in reaching the kernel of the matter. But I would fain see in Professor Allbutt's references to Pawinski's work the loosening of a too exclusive attachment to the aortic theory of angina pectoris as published, for example, in his Lane lectures, although some of Pawinski's cases do not present a very striking likeness to the classical features of Heberden's disease.

I am, Sirs, yours faithfully,
ALEXANDER MORISON.
Upper Berkeley-street, W., July 25th, 1893.

THE SOCIETY OF APOTHECARIES OF LONDON AND THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—I must, on behalf of the Society of Apothecaries of London, take exception to the leading article in THE LANCET of July 25th, p. 242, commenting upon the recent meeting of the General Medical Council and the consideration which then took place of the reports upon the primary examinations of the Conjoint Board and of the Society of Apothecaries. In dealing with the question of the first year's study the statement is made that the Society, following in the wake of the Conjoint Board, has so far failed to carry out the spirit of the recommendation of the Council that it has accepted the last year of study of any boys' school, in which there might be a pretence of playing at science teaching, as the first year of the medical curriculum. I am not concerned to inquire whether this is or is not a correct description of the teaching institutions recognised by the Conjoint Board but not approved by the General Medical Council, to which institutions I assume the statement alludes, but in justice to the Society of Apothecaries I must point out that only candidates who have studied either at medical schools or at institutions recognised by the Council are admitted to the Society's primary examination.

I also regret to notice in the article statements which appear to link the Society with the Royal Colleges in what is termed an "opposition" to the General Medical Council, an "opposition" which, in the case of the Society, I have no hesitation in saying, is entirely non-existent. The Society of Apothecaries is now, and always has been, most anxious to work loyally and to the best of its ability with the Council and has, in fact, consistently done so, recognising fully that the strength and usefulness of the Council can best be maintained by generous coöperation on the part of the licensing corporations; and it has certainly at no time in the past taken up the position, in the words of your article, of "defending its rights and privileges" against "aggression" on the part of the Council, nor does it intend to do so now. I think it is only necessary to refer to the conciliatory terms of the Society's reply to the recent visitors' report on the primary examination to recognise that it is entirely beside the mark to ascribe any intention of hostility or opposition on the part of the Society to the General Medical Council.

I am, Sirs, yours faithfully,
A. MOWBRAY UPTON,
Clerk to the Society.
July 28th, 1903.

THE OVERTRAINING OF MIDWIVES.

To the Editors of THE LANCET.

SIRS,—It is understood that the Midwives Board is formulating the rules for the training of midwives under the Midwives Act. May I, as one who has in a humble way supported legislation in the interest of the poorer classes of women who have to rely in the hour of their need on midwives, claim to say a word at this juncture? There is a tendency, perhaps a natural tendency, now that the Act has been gained to overdo what was meant to be done by it—in other words, to overtrain instead of training the midwife and to make her superior to the work required of her—viz., to attend poor women in ordinary confinements, to nurse them for a week or ten days afterwards, and on the occurrence of any irregularity or abnormality in mother or child to apply for medical advice and assistance. If this tendency to overtrain is not checked the full blessings of the Act will not be realised. If the midwife is to be trained for two years as a nurse, as suggested at a recent drawing-room meeting, she will be trained beyond the nature and scope of her duties, her price will become prohibitive, and the poor will be driven to resort to all sorts of makeshifts to dispense with her services and will encounter the same risks as at present. I am told by one who ought to know that the extension of the midwives' training even to six months will seriously reduce the number of pupil midwives. To understand the tendency to overtraining and its disadvantages we have only to look at what has happened in the nursing calling. A trained nurse now costs at the rate of from 100 to 150 guineas a year. She (or he) has become a luxury beyond the reach of large sections of the community where there are many cases in which a nurse is more or less needed, though the services required are simple and do not call for the amount of training which is now given. Speaking as a general practitioner this seems to me a serious question. But I am concerned for the moment at the tendency of some of those who have most humanely fought for the training of midwives to carry it to excess. I am sure the friends of poor lying-in women will not misunderstand me when I suggest that they will do well to proceed tentatively and slowly. Two points ought to be remembered. Firstly, that the law contemplates that midwifery is still to be under the care of the medical profession and that in all its unusual forms the midwife is to seek medical assistance. Secondly, our maternity charities show well that with the present training of three months, even in very humble homes, the lying-in mortality is reduced to very small proportions.

I have before me the report of the City of London Lying-in Hospital for the year ending 1902. Of 2242 women delivered by the midwives at their own homes (subject, of course, to the supervision of the medical staff) only two women and 31 children died. It seems reasonable to think that the Midwives Board will do well in the first instance to require but little extension of the same training that has been hitherto found to be sufficient and not to endanger the success of the new Act by pitching too high the standard of education.

I am, Sirs, yours faithfully,
J. G. GLOVER.
Highbury-place, N., July 27th, 1903.

LONDON RECEIVING HOUSES FOR THE UNSOUND IN MIND.

To the Editors of THE LANCET.

SIRS,—I have just had an opportunity of reading the Bill for the establishment of these houses in the metropolis which has been sent down by the House of Lords to the House of Commons and which will shortly be discussed there. It bears the stamp of careful consideration of all matters vital to the carrying out of the scheme successfully and it is calculated to meet a pressing need, always recognised by those who, like myself, have long been engaged in caring for the unsound in mind in the great institutions of the metropolitan counties and district. But there is one point in the Bill to which I should like to call very especial attention, and that is its phraseology [illegible] measure in most respects, it [illegible] a misnomer, and that of a [illegible] kind. I refer to the word "lunatic."

What, I ask, is the real necessity for continuing the use of what is now considered an inaccurate and opprobrious epithet? What have mental disorders to do with the moon? No doubt such disorders do sometimes recur and pass through their phases, but can it be shown or proved that those phases are always coincident with phases of the moon or has it ever been proved that the moon produces or even influences mental disorders? Turning to Dr. D. Hack Tuke's "Dictionary of Psychological Medicine" we find the word "lunatic" defined thus: "(Luna, the moon, from its *supposed influence* in *causing* mental disease) A term applied to those diseases considered to be *under the influence* of the moon's phases, &c." The Act 16 & 17 Vict. Cap. 97, declares that the term "lunatic" shall mean and "include *every person* of unsound mind and every person being an idiot," thus including the mildest as well as the most serious disorders of the mind. It is, doubtless, the established and probably convenient legal term, but possibly we of the long-suffering medical profession have been dominated by so-called legal necessities and technicalities too long for the advantage of progressive medicine in that department, especially wherein it deals with diseases and disorders of the great nerve centres. Surely, if there still exist the skill and erudition of some person, be he legal or be he medical, will devise some words better indicating fact and more appropriate generally than the words "lunatic" and "lunacy."

Before closing this letter I would remark that the Bill in question invites the application of out-patients for relief to those receiving houses. I can imagine some such would-be out-patient debating in his own mind before making such an application the questions, "Am I or am I not a 'lunatic'?" "Am I or am I not entitled to the relief offered here?" and turning sorrowfully away, unable or unwilling to admit the soft impeachment and being thereupon for ever afterwards a chronicled "lunatic."—I am, Sirs, yours faithfully,

West Malling, Kent, July 25th, 1903. JAMES ADAM.

THE TREATMENT OF GOITRE BY THE USE OF DISTILLED OR RAIN WATER.

To the Editors of THE LANCET.

SIRS,—With regard to the letters of Dr. C. A. Rayne and Dr. W. H. B. Brook in THE LANCET of July 18th (p. 185) and 25th (p. 265), I may say that the use of rain and distilled waters is no new thing in the treatment of goitre. It has been familiar to physicians in diverse parts of the world for a long time. Several cases of cure by this means have occurred in my own practice, as I pointed out in a paper read some years ago at Carlisle at a meeting of the Border Branch of the British Medical Association. I do not think that the cure depends on either rain or distilled water as a matter of fact, but on the fact that the patient is drinking a fluid free from the goitrous poison and in proof of this I may quote the following instance from the writings of St. Lager. "Keyssler says that round Schemnitz in Hungary the goitrigenous action of the waters is so evident that those who go to drink the water of a neighbouring valley have the satisfaction of seeing their tumours disappear." Many similar instances could be quoted. Here is an interesting one, also from St. Lager. "Military surgeons who have observed epidemics of goitre at Clermont and several other towns noticed that the officers and non-commissioned officers who only drank wine escaped the disease." It is a remarkable fact that goitre is unknown in places where rain water only is used—e.g., Constantinople, Venice, parts of Holland and Belgium, &c. Cardinal Billiet has put on record a remarkable case of goitre incidence occurring in the village of Puiset in Planaise. Here he found 17 families more or less afflicted with goitre and cretinism from using the spring water of the country. One family was absolutely healthy and used rain-water only. The best results are obtained, of course, in cases of recently formed goitres as when a considerable amount of fibrous tissue is formed the results are not so good although frequently remarkable.

I am, Sirs, yours faithfully,
LOUIS E. STEVENSON, M.B., &c., F.G.S.
Temple Sowerby, Penrith, July 25th, 1903.

To the Editors of THE LANCET.

SIRS,—The letters in the two last issues of THE LANCET on the use of distilled or rain water in goitre induce me to give briefly my own experience. For the last seven years I have directed patients with goitre to drink distilled water or boiled rain water. During this period I have treated about a dozen cases, some of them from other districts. I cannot say that all have been successful; one patient, a woman with a large goitre of many years standing, died; another took distilled water in considerable quantities for six months, but there was no improvement and she was finally cured by hydrofluoric acid. In this case I am confident that the patient always took the distilled water and continued to do so for 18 months after her cure. Of the other cases all were wholly or partially cured, but I cannot be certain that they always carried out the treatment. The conclusion I have come to is that distilled water is a valuable adjunct in the treatment of goitre, but not of itself a specific. It would be interesting to hear the experience of others on this point.

I am, Sirs, yours faithfully,
ARTHUR C. WILSON, M.B., Ch.B. Vict.
Formby, July 26th, 1903.

MEDICAL DOCTRINES OF HEREDITY.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 25th, p. 264, Dr. C. R. Niven takes me to task for having, as he conceives, misrepresented Dr. G. Archdall Reid's position as set forth in that gentleman's letter to you of July 4th, p. 56. Dr. Reid is, I am sure, well able to take care of himself and will be able to judge whether I have misconstrued his position, but I contend that the very passage which Dr. Niven quotes from Dr. Reid's letter fully bears out the construction put on it. Dr. Reid says: "Even if the germ cells are injured, it does not follow that this injury will be perpetuated in their very remote descendants—i.e., in the body cells of the child—at a time long after the injurious agency has ceased to act" and he implies his disbelief in the possibility of such injury being so perpetuated, his whole argument, indeed, being devoted to substantiating that position, which position, if correct, certainly implies that the germ plasm is incapable of receiving permanent injury by the agency of poisons circulating in the blood—that is, of course, that the damage to individual germ cells is never of such a nature as to lead to permanent alteration in the organism which results therefrom. If any injury has been inflicted on the germ cells of a parent by the action of a poison circulating in the blood this can only be judged of by its effects on the offspring. Either a modification can be produced in the somatic cells of a child as a result of such influence or it cannot. If as a result of the development of germ cells in a vitiated nutrient medium the child resulting therefrom is modified in any direction, however slight, then a definite germinal variation has been produced through the agency of the poison in question. If, however, the effect, if any, produced on the germ cells is always more or less evanescent, and if no permanent alteration can be produced in the somatic cells of the child thereby, then it necessarily follows that the child has not been modified in any way and that no harm of any kind has been produced. As the well-being of the offspring is the only thing with which we are here concerned it is a necessary conclusion that if this cannot be permanently injured by the action of poisons on the germ cells of the parent, then it is a matter of indifference as regards the welfare of such offspring whether the germ cells from which it arises are developed in a vitiated nutrient medium or the reverse.

Dr. Niven devotes a portion of his letter to creating for me an imaginary position and then proceeding to criticise it. I suggested that there might be causes of variation other than those comprised in the union of two dissimilar germ plasms, the context clearly showing that I was referring to the possibility of such variation occurring by the direct action of poisons on the germ plasm; but Dr. Niven chooses to assume that I was arguing in favour of the transmission of acquired characters. I argued nothing of the sort and there is not a line in my letter suggesting any opinion of the kind. As a matter of fact, I am entirely in harmony with Dr. Reid as to the non-transmission of acquired characters and have elsewhere[1] expressed myself in favour of the view that on this question "the Weismannian position at present holds the field." It is therefore somewhat superfluous for Dr. Niven to ask me for proof of doctrine which I do not hold and which was in no way raised in my letter. Dr. Niven goes on to say that if injury is done to the growth of the embryo during the pregnancy of a drunken mother that is not a problem in heredity. I never suggested that it was. I have indeed elsewhere[2] drawn attention to the fact that in these cases any injury done to the germ plasm "will be added to, and reinforced by, chronic alcoholic poisoning of the nervous centres of the embryo during the whole period of intra-uterine life." The condition of the mother during the intra-uterine life of the child is one of the disturbing factors which have to be taken into account in endeavouring to form an estimate as to the effect of poisons upon the germ plasm itself, but in the case of alcohol this disturbing factor can often be entirely eliminated as innumerable cases exist of the union of drunken fathers with sober mothers. I am not disputing the general position which Dr. Reid has so frequently insisted on and which Dr. Niven adopts—viz., that nations are sober in proportion to their past experience of alcohol. I think it probable that such an evolution of alcohol-resistant communities has been and is going on, though I would remind Dr. Niven of the striking example afforded by the Mohammedan races which show us millions of human beings who are perfectly sober not by virtue of such an evolution, but in consequence of the operation of religious sanctions. Where I differ from Dr. Reid and Dr. Niven is in the position they take up that an unfavourable variation such as would presumably be produced by the action of alcohol on the germ plasm of the parents would necessarily go on accumulating from generation to generation until the whole race became extinct Whether it did go on so accumulating or not would depend largely upon the nature of the germ plasm with which it united in the act of fertilisation. Even when many molecules of one germ cell are modified in the direction of instability these may be counteracted and controlled by more stable molecules belonging to the other germ cell and the offspring thus conditioned may be free from taint, a degeneracy which has been begun may therefore be eliminated altogether in future generations As a matter of fact, such a process of elimination of parental taint by reversion to a more stable ancestry is continually going on side by side with one which reinforces and adds to the degeneracy There is a great tendency to regression towards the mean standard of the race, as Galton has shown us, and the more persistent nature of racial characters as compared with individual ones, whilst it renders progress of a healthy kind less rapid than it would otherwise be, has also a preservative influence in the opposite direction I think that the inhabitants of the British Islands may fairly be described as "very drunken", nevertheless, it cannot, I think, be denied that we have abundance of stable germ plasms in our midst ready, it may be, to neutralise the unstable elements of other germ plasms, rendered such by the action of alcohol, or to supplant these latter altogether

---

[1] Journal of Mental Science, October, 1902.
[2] Ibid.

But, in truth, the laws of heredity are so intricate and we are still so ignorant of their mode of operation that dogmatism in either direction is out of place The exact experiments which might settle the question cannot, of course, be conducted on the human subject, but it might be possible to obtain results of value by administering alcohol to some of the lower animals such as anthropoid apes or dogs and noting the effect on the progeny It would, of course, be necessary to give the alcohol in sufficient quantity and for a long enough period of time to get the tissues thoroughly saturated with the poison—to simulate, in fact, the sodden tissues of the chronic alcoholic—and it should be stopped directly conception had been permitted to take place The relatively undeveloped brains of these animals would render impossible an exact comparison with the human subject, but the experiment would be worth a trial

In the meantime, I contend that the remarkable frequency with which alcoholism is found in the family antecedents of those who suffer from insanity or the milder forms of mental instability furnishes a *primâ facie* case against alcohol—that is, in favour of the view that the molecules of the germ cells of the parent are capable of having their development modified by the circulation of alcohol in the blood in such a [illegible] parentage are as stable and healthy as those of parents not so circumstanced?—I am, Sirs, yours faithfully,

Rainhill, July 26th, 1903 J WIGLESWORTH

THE ROENTGEN RAYS IN THE DIAGNOSIS OF PULMONARY DISEASE

To the Editors of THE LANCET

SIRS,—It is becoming customary on the part of those who are more or less enthusiastic over the x rays to assert that cases of pulmonary tuberculosis can be detected by these means at an earlier stage and with greater certainty than is possible by the time honoured method of inspection, percussion, and auscultation in its various applications and refinements. In certain recent communications to THE LANCET[1] this view is upheld and it is therefore with pleasure that one turns to the article of Dr David Lawson and Mr Hill Crombie[2] in which a temperate and carefully expressed opinion is pronounced as to certain facts elicited by radioscopy As, however, the claims put forward by some on behalf of the x rays are such as might lead the unwary to imagine that it is absolutely necessary for them to procure an x ray apparatus in order to do justice to their patients and themselves, I venture to express the opinion that not only are the x rays as a means of diagnosis in early phthisis less valuable and less exact than the ordinary methods, but that in addition, what results they do yield are very frequently unreliable and at the best are difficult of interpretation

Now, this statement is not made in any spirit of prejudice against the recent science of radioscopy. In the hands of those who have had long practice in its use it is frequently of excellent service in many intrathoracic conditions, more especially in the case of deep seated tumours, and also, it may be added, as an aid in the diagnosis of pulmonary tuberculosis, but as regards its superiority in the detection of the earliest stage of phthisis statements of a delusive character are being made

I may preface the brief observations which follow by observing that x ray workers do not, as a rule, detail the examination by percussion, auscultation, &c., which they have conducted in order to check the results of radioscopy in the diagnosis of early tuberculosis. It may be stated that over a certain area, such and such a note was all that could be elicited, or that the breath sounds were doubtfully so and so, but for anything like a minute, systematic, and exhaustive examination one usually searches their records in vain But if such a careful detailed examination be not recorded alongside the results of radioscopy, then these results are valueless as comparative data, however confident the assertions based on them

It is admitted by all radioscopists that it is only in the stage of consolidation, or in other words, after a number of tubercles have fused together so as to form a caseous mass in the lung, that the rays are of any service Dr Lawson remarks that the earliest reliable indication of disease affecting an apex is its "failure to light up on the screen at full inspiration to the same extent as the non affected apex does This negative quality," he says, "is absolutely diagnostic, either of an active or an arrested lesion This property also enables one to define the level of the apex of the lungs on each side respectively—a point in diagnosis to which many attach much importance" Now it can scarcely be supposed that the most devoted adherent of x rayism would allege that such an apex was insusceptible of ordinary diagnosis On the other hand, I should say that refined tests would indicate commencing involvement of an apex at a considerably earlier stage than that above described, and indeed at a time which may be called pre tuberculous—i e, when there is merely comparative impairment of the elasticity of one lung Such diagnostic tests include the various methods of estimating and comparing the apical excursion on both sides and the "segmental" method as described by the writer[3] Such tests, also, can differentiate with certainty between an active and an arrested lesion, which, as Dr Lawson observes, cannot be effected by the x rays

A sign which has been made much of by radioscopists as denoting either the pre tuberculous stage or else the deposition of isolated tubercles is a restriction in the excursion of the diaphragm on one side during deep inspirations It may be true that this phenomenon has obtained prominence since the introduction of radioscopy, but whatever value is to be attached to it, it can be determined with perfect accuracy by the following means (1) by inspection—Litten's sign—when, with the patient lying in the correct position against the light, the diaphragm shadow can be seen as a thin dark line moving up and down the side of the chest, (2) by percussion, in the form of "limitary percussion"[4], (3) by auscultation, especially the vocal resonance, the patient having first drawn a deep breath and the stethoscope moved upwards as he expires and counts audibly, and (4) by auscultatory resonance, by means of a tuning fork, a delicate test by which, with the stethoscope placed over the organ and the tuning fork brought towards it, the edge of the lung can be sharply demarcated during inspiration and expiration These manœuvres, in the hands of those who have practised them, will define the diaphragm excursion as accurately as the x rays. It is, however, to be noted that this "diaphragm sign" is variable, not always trustworthy, and certainly not applicable to all cases It is easy to see that basal conditions affect it greatly and the same, though to a much less extent, may be said of certain abdominal conditions. First described by F H Williams of Boston several years ago and largely quoted since, that acute observer pointed out two facts worth remembering one that in the healthy chest the excursion on the right side is normally greater in forced inspiration than that on the left side, and the other, that in certain early cases of tuberculosis although the inspiratory excursion was shortened on the affected side, yet in forced expiration the diaphragm rose higher on the diseased side, in this way the range being about equal on the two sides of the sick from the bites of mosquitoes. He says: "In the city of Havana alone mosquitoes have been killed to extirpate yellow fever. In no other city or town in Cuba has this measure been put into practice and yet yellow fever has disappeared, not only from Havana, but equally as well from all the other cities and towns." The argument of Dr. Ybarra, as of many Southern physicians, is that improved sanitary and hygienic measures are the true cause of the apparent extirpation of yellow fever in Cuba. Nevertheless, the fact cannot be evaded that the late Dr. Reed and his colleagues conclusively proved that yellow fever is spread by mosquitoes. Accordingly the extirpation of mosquitoes in Cuba should be carried on with undiminished zeal.

A Parasite Fatal to the Mosquito.

Dr. Charles Wardell Stiles, of the United States Public Health and Marine Hospital Service, claims to have discovered and isolated a parasite which kills those mosquitoes which it infests. Professor John B. Smith, of Rutgers College, forwarded to Dr. Stiles for examination two worms which had been taken from the abdominal cavity of New Jersey mosquitoes. Dr. Stiles decided that these specimens were larval round-worms belonging to the family mermithidæ and named the parasite "agamomermis culicis." The New York *Sun* referring to the matter states that the mosquitoes infested with the parasite are sluggish in their movements and do not live long and that the females infected do not breed. It is further announced that the Public Health and Marine Hospital Service intends to undertake experiments on a large scale with a view to propagate the "mosquito destroyer," thereby attempting to exterminate mosquitoes in the United States.

Statistics of Suicide in the United States.

Professor Bailey, of Yale University, has for several years interested himself in the question of suicide and has published statistics of suicide in the United States from 1897 to 1901. The Chicago *Tribune* has also kept a similar record, but whereas Professor Bailey has collected his statistics for a period of four years only the *Tribune* has done so for 18 years. Professor Bailey publishes a total of 29,344 cases of suicide during the four years, while for the same period the *Tribune* recorded 30,462. Professor Bailey finds that "shooting is the favourite method of suicide, followed closely by poison. Almost 60 per cent. of the cases of suicide are included under these two heads." The *Tribune* remarks that this may have been true at the time of writing but is so no longer. Since the end of the year 1900 up to the present time the number of self-inflicted deaths by poison has considerably exceeded the number by shooting. The increase in poisoning is attributed to the ease with which certain poisons, and notably carbolic acid, can be procured. Professor Bailey states, reasoning from his figures, that in general the proportion of suicides of males to that of females is about three and a half to one. The *Tribune*, however, judging from later statistics asserts that such is not now the case. At the present time the ratio is less than three to one, and the number of women committing suicide is increasing faster proportionally than the number of male suicides.

General Army Hospital in Washington.

Under an Act passed during the last session of Congress the Surgeon-General of the United States Army is having a sketch made of the arrangement of a group of buildings to serve as a general army hospital in Washington. There has, however, as yet been no appropriation made either for the purchase of the site or for the erection of the buildings.

July 17th.

Obituary.

SAMUEL FARRANT, M.R.C.S. ENG., L.S.A.,

HONORARY CONSULTING SURGEON TO THE TAUNTON AND SOMERSET HOSPITAL.

MR. SAMUEL FARRANT died at his country residence, Amherd, Pitminster, on July 18th, in his sixty-sixth year, from heart failure. Mr. Farrant went to Taunton in early life as pupil to the late Mr. C. H. Cornish and on becoming qualified he commenced practice in the town and continued it up to his death. He was for a long period honorary surgeon to the Taunton and Somerset Hospital and upon his retirement a short time ago he was elected honorary consulting surgeon. Mr. Farrant had an extensive practice and a considerable reputation as an ophthalmic surgeon. He took a great interest in municipal matters and was at one time mayor of Taunton. He was also a surgeon-lieutenant-colonel of the West Somerset Imperial Yeomanry. Mr. Farrant was a strong Churchman and had filled the office of churchwarden at both St. Mary's and St. James's churches. He initiated and carried out a restoration of the latter church a few years ago.

Mr. Farrant was for 40 years one of the district medical officers of the Taunton board of guardians. The deceased was one of the representatives of Taunton on the Somerset county council at the time of his death. He enjoyed great popularity in Taunton and much sympathy is felt there for his widow and children. At the funeral, which took place at St. Mary's cemetery, Taunton, on July 22nd, the mayor and corporation attended in state and representatives of the various public bodies with which the deceased was connected were also present, including a considerable number of members of the West Somerset Imperial Yeomanry, headed by the commandant (Colonel Barratt, J.P.).

JOHN ALEXANDER COOKSEY, M.R.C.P. EDIN., M.R.C.S. ENG.

MR. J. A. COOKSEY, whose death took place on July 19th, at his residence, The Lynches, Malvern, was the eldest son of John Haynes Cooksey and was born at Worcester on May 15th, 1820. The family have been connected with the county for centuries and were formerly considerable landed proprietors. The deceased was educated at the High School, Edinburgh. He was a favourite pupil of the late Mr. Carden of Worcester, a well-known surgeon, and he completed his medical course at St. George's Hospital, London. In 1845 he became M.R.C.S. Eng., in 1859 L.R.C.P., and in 1878 M.R.C.P. Edin. After working with the late Dr. John Berry for about two years at Coventry he purchased a practice at Chipping Campden, Gloucestershire. There he remained for about 15 years, during which time the practice greatly increased. In his comparatively early Chipping Campden days an action was brought against him, but the charge was so utterly without any foundation that when the day for the trial came counsel withdrew the case. The action aroused widespread sympathy and a testimonial was presented to the defendant consisting of both plate and money. In 1863 he sold his practice at Chipping Campden and settled at Malvern, where he practised for 21 years and took an active part in the erection of the rural hospital and other local improvements. In 1876 he again appeared as defendant in court, but he won an easy victory, the jury not thinking it necessary even to hear all the witnesses for the defence and declaring that he left the court without the slightest stain on either his professional or private character. The action had aroused much interest in Malvern and a second testimonial was presented to Mr. Cooksey. He retired from practice in 1884, chiefly on account of deafness, being succeeded by the late Dr. Prothero, with whom he had been in partnership for two years.

NATIONAL ORTHOPÆDIC AND ROYAL ORTHOPÆDIC HOSPITALS.—At a special meeting of the governors of the National Orthopædic Hospital on July 24th, held at the hospital in Great Portland-street, London, the following motion was duly passed:—

> That the amalgamation of the National Orthopædic Hospital and the Royal Orthopædic Hospital on the arrangements agreed upon at the meeting of the committee of management held on March 20th, 1903, is approved of.

Before this resolution was formally adopted the chairman, Mr. Robert Cooper, read out the following letter signed by Mr. E. Muirhead Little, honorary secretary of the medical board of the hospital:—

July 22nd, 1903

DEAR SIR,—At a meeting of the medical board held at the hospital this afternoon I was desired to ask you to lay before the governors at their special general meeting on the 24th inst. the following resolution which was unanimously passed by the board: "That it having been reported in the press that on amalgamation of the 'Royal' and the 'National' Orthopædic Hospitals the surgical staffs of the two hospitals as at present constituted would be joi[illegible] this [illegible] to [illegible] of [illegible] to [illegible] tion [illegible] opinion that all members of the surgic[illegible] hospitals—without any exception—must [illegible] stipulation they have understood from th[illegible] of management has always been put forward by him in the negotiations with the King's Hospital Fund.'

THE
BRITISH MEDICAL ASSOCIATION.
MEETING AT SWANSEA.

The meeting of the British Medical Association at Swansea marks its seventy-first anniversary, and this is, we believe, the first occasion upon which the association has selected Swansea for its annual congress.

We may repeat with regard to Swansea what we said last year concerning Manchester—it is not a lovely city. The critics who are ready to point out that medical and other scientific congresses have much lost their serious value, having developed, or rather degenerated, into picnics, must acquit the executive of the British Medical Association of choosing in Swansea a place the intrinsic attractions of which will draw members away from the meetings of the sections. But Swansea was not always ugly. It has become so in the course of its commercial development, in passing from what it was in the old days, a much patronised health resort, to a busy industrial centre. The health-giving properties of the environment of both sea and country, however, remain and numerous little health resorts have sprung up to the westward in Swansea Bay extending to the Mumbles and beyond to Langland Bay. Here the scenery is most interesting, the coast being of a wild and rugged type, like that of Cornwall, bounded with steep crags of greystone. This beautiful district is locally known as the Mentone of South Wales, the name being due to the curious mania that we have as a nation of belittling our own natural beauties by nicknaming picturesque localities after foreign places. The title of "Mentone" would seem to be justified from the fact that while in winter the weather is genial and mild, the inland heights serving as a source of protection from the north and east winds, in summer it is bracing. The temperature keeps within the limits of the temperate zone, but a somewhat heavy rainfall is annually recorded. The weather is frequently of the Atlantic type. Towards Langland Bay may be seen groups of plants and trees which are characteristic of southern stations, such as Torquay or the Riviera.

But Swansea proper is now a purely commercial centre and by the Association's decision to hold the annual meeting in Swansea this year medical men have found themselves gathered together in a busy shipping centre with evidences of docks, foundries, collieries, and busy markets on all sides, and through some of the streets are railways for heavy mineral traffic, recalling busy places in the vicinity of the docks of London or Liverpool. The industrial progress of Swansea has been enormous during past years owing to the rapid development of coal-mines and of a big mineral trade directed chiefly to the smelting of copper, iron, and nickel. But the greatest of all industries perhaps is the tinplate trade, this class of goods being exported in enormous quantities to all parts of the world. Within a four-mile area it is stated that there are close upon 200 works in Swansea. Not far from Swansea is Landore which is a huge blot both on the land- and sea-scape. By day it is seen to be smothered in a cloud of black smoke and by night it has the weird, uncanny aspect of a valley full of many-coloured blazing chimneys and furnaces. It is obvious that the chief occupations of the inhabitants of Swansea call frequently for surgical and medical aid and the town has an excellent equipment in this regard, as exemplified by the Swansea Hospital and several dispensaries. There is also an institution for the deaf, dumb, and blind.

The annual museum was held in the public library in the Alexandra-road. The organising committee evidently met with some difficulty in providing a suitable place for the purpose. Otherwise it might be imagined that a drill-hall or some other building of plain description would have been chosen instead of the rooms and corridors of an art gallery. The exhibitors, at any rate, ought to be pleased with the space placed at their disposal and with its attractive surroundings in the shape of pictures, statuary, and other art productions. There was, however, some difficulty experienced in placing the exhibits to the best advantage owing to the very proper restrictions laid down by the authorities as to the use of nails or hoardings on the walls. The pictures were thus left in their position, but some of the statues had of necessity to be removed. The exhibits occupied the ground-floor and the first and second floors of the building. Those exhibitors who occupied the ground-floor were decidedly favoured, for at first sight the visitors concluded that the exhibition was limited to that floor. Owing probably to the rainy weather on Tuesday a very good start was made and the influx of interested persons almost reached crowding point. Several local firms were represented. In another column we commence an article descriptive of the interesting exhibits of foods, drugs, and sanitary and medical appliances.

At the first general meeting H.R.H. the Prince of Wales was elected an honorary member of the British Medical Association. "Not only for the honour his membership will confer on the Association, but for the distinguished services His Royal Highness has rendered to the medical profession," were the words of the motion recommending the election which we need hardly say was unanimous. This was a fitting sequel to the precedent created some few years ago when His Majesty the King, then Prince of Wales, gave one of his numerous proofs of interest in the medical profession by accepting the honorary membership of the Association. So recently as last month the Prince of Wales was showing similar interest in a most useful and practical manner by presiding at the festival dinner of the Royal Medical Benevolent College with most satisfactory results to that excellent institution, and there is no doubt that in the Heir Apparent we have a friend to scientific and medical progress who will be ready to use his exalted position for the general advancement. A telegram was received from His Royal Highness during the meeting thanking the Association for the honour conferred on him. Dr. T. D. Griffiths afterwards delivered the presidential address, which will be found in another column.

The Address in Medicine, which we also publish this week was delivered by Dr. Frederick T. Roberts, senior physician to University College Hospital, London, on Wednesday evening.

The local entertainment sub-committee, under the chairmanship of Mr. Jabez Thomas, has worked hard to provide recreation for the members and to furnish them with opportunities for seeing the sights of the neighbourhood. One of the most popular of the many garden parties held in honour of the visit of the Association was that given on Tuesday, July 28th, by Mr. and Mrs. William Walters at their delightful residence overlooking the Bay of Swansea at Ffynone. Though the weather was somewhat unpropitious the lovely grounds were thronged with visitors who admired the many beautiful views to be seen from the well-kept lawns. On Wednesday and Thursday excursions were arranged to the Towy Valley, Bishopstown Valley, Caswell Bay, Oystermouth Castle, and Clyne Castle, while cricket and golf matches were also arranged, but the weather dislocated nearly all plans.

The want of sufficient accommodation in Swansea, owing partly to the clashing of the assizes with the meeting of the

British Medical Association, has been partly met by the formation of a camp on a beautiful site a little beyond the Mumbles. 13 members of the Association availed themselves of this opportunity of enjoying fresh air and each was provided with a tent to himself. The general arrangements of the encampment were on the lines of an officers' mess. The occupants of the tents were made honorary members of the local yacht club and had a thoroughly enjoyable experience, the splendid view of the surrounding country and the general feeling of independence and freedom compensating them for the inclemency of the elements. The success of this effort to solve the housing question was largely due to the kindness and courtesy of Captain Thomas of the local volunteers, and the example furnished might well be imitated on future occasions when the Association is holding its meeting in a town of limited accommodation.

The usual service took place on Tuesday at the parish church. The church was fairly well filled and the Mayor and corporation attended in state. The sermon was preached by the Lord Bishop of St. David's from the text, "Christ also suffered" (St. Peter ii., 21), and the alms were, as usual, divided between Epsom College and the British Medical Benevolent Fund.

Much praise is due to Mr. Guy Elliston, the general secretary of the Association, for his untiring energy to promote the smooth working of the machinery of this the first annual meeting over which he has had undivided business control. Our thanks are also due to him and to his staff for their kindness to our representatives in many directions.

For the accommodation afforded to our staff at Swansea we tender our thanks to Mr. Ebenezer Davies, the medical officer of health, who very kindly placed his offices at our disposal and rendered us much assistance thereby.

The seventy-second annual meeting of the Association will be held at Oxford in 1904, Dr. William Collier, senior physician of the Radcliffe Infirmary, being nominated as President-elect.

THE GENERAL MEETINGS.

THE FIRST GENERAL MEETING.

The First General Meeting was held in the King's Hall on July 28th at 2 P.M.

The retiring President, Mr. WALTER WHITEHEAD, took the chair and introduced the President-elect, Dr. Thomas Dryslwyn Griffiths, late physician to the Swansea Infirmary and ophthalmic surgeon to the Swansea Hospital.

Dr. GRIFFITHS then took the chair and the official badge was presented to him by Mr. W. F. Brook, one of the local honorary secretaries. After thanking the Association for electing him to his high office, he remarked that his first official duty was a most pleasing one—to announce that His Royal Highness the Prince of Wales had consented to accept the honorary membership of the Association. He had therefore much pleasure in moving:—

> That His Royal Highness the Prince of Wales be and is hereby elected an honorary member of the British Medical Association, not only for the honour his membership will confer on the Association, but for the distinguished services his Royal Highness has rendered to the medical profession.

The President of the Council, Mr. ANDREW CLARK, seconded the motion, which was carried with acclamation, the audience rising and singing "God bless the Prince of Wales," Dr. S. Cromwell Jones singing the solo.

Dr. G. B. FERGUSON, in a well-chosen speech, proposed a vote of thanks to the retiring President, Mr. Whitehead, which was unanimously agreed to, as was also the proposition that he should be elected a vice-president for life.

Mr. WHITEHEAD, in replying, expressed his gratification for the honour conferred on him and as an encouragement to the President for the year he would say that his year of office had been one of the most pleasant of his life.

The PRESIDENT then vacated the chair in favour of the chairman of the Council and the financial statement was submitted to the meeting by the treasurer, Dr. E. M. SKERRITT. A breezy discussion ensued, Dr. ROBERT BELL taking exception to the meagreness of detail offered to the members in the accounts. He wanted to see more profit out of a revenue of £40,000.

The speaker was interrupted repeatedly in the course of his remarks and the meeting clearly did not appreciate his views. Several members defended the Council and the treasurer made an effective reply, after which the financial statement was adopted.

Dr. H. W. LANGLEY BROWNE proposed that a grant of £300 should be added to the nucleus of £500 which already existed to form a superannuation fund for the office staff when overtaken by age or sickness, which, after some discussion *pro* and *con*, was agreed to.

The meeting was then adjourned.

THE (ADJOURNED) FIRST GENERAL MEETING.

The adjourned first general meeting took place in the evening at the Albert Hall, which was well filled by the members, while many guests were present, including a large number of ladies. The platform was tastefully decorated and the Morriston Male Voice Party sang several pieces. The Mayor of Swansea (Mr. Griffith Thomas) welcomed the members of the British Medical Association to the town and introduced the new President.

The PRESIDENT then announced that the Prince of Wales had that afternoon been elected an honorary member of the Association and read a telegram which he had received from His Royal Highness, which was as follows:—

> In thanking you for your kind telegram I beg to convey to the Association my appreciation of the resolution passed to-day. I feel very proud to have been elected an honorary member and I wish the British Medical Association all prosperity.—GEORGE.

The Stewart prize was then presented to Dr. F. W. Mott for his researches into the causes and prevention of dysentery in asylums and the reception of foreign and colonial guests followed.

Dr. GRIFFITHS then delivered his Presidential address which we publish at p. 281. Votes of thanks to the President and to the Mayor of Swansea concluded the proceedings.

THE SECOND GENERAL MEETING.

The second general meeting was held in the King's Hall on July 29th. The proceedings only lasted a few minutes and consisted in the announcement that the meeting of 1904 would be held at Oxford and that Dr. William Collier would be the President.

THE SECTIONS.

MEDICINE.

WEDNESDAY, JULY 29TH.

Medical Treatment of Inflammations in the Cæcal Region.

After a few introductory remarks by Dr. C. T. VACHELL (Cardiff), one of the vice-presidents of the section who occupied the chair, a discussion on the above subject was opened by Dr. P. M. CHAPMAN (Hereford). In cases of appendicitis, he remarked, the question of surgical interference was a very important one, and in Dr. Chapman's view surgical measures were to be avoided if possible. The main responsibility for the treatment of cases of appendicitis rested primarily with the physician and many of these patients recovered by expectant treatment. He had met with several cases in which abdominal explorations had been attended with disastrous results. He tendered an apology for the brevity of his remarks owing to the shortness of the notice which he had received.

Dr. H. W. KING (Chester) wished to confirm the views expressed by Dr. Chapman. Many cases would do much better with hot fomentations, aperients, and small doses of opium. Belladonna and hyoscyamus sometimes promoted the action of the bowels.

Dr. T. D. **SAVILL** (London) thought that a large number of cases of appendicitis and other inflammations in or around the cæcum were preceded by chronic catarrhal colitis, as distinct from membranous or ulcerative colitis, and important preventive measures might be adopted by the recognition and treatment of this form of colitis. The mucus in the stools was apt to be overlooked by the patient and his medical man and these patients sometimes came under notice for neurasthenia, malaise, or malnutrition of indeterminate origin. The treatment consisted mainly of regulated diet, the administration of intestinal antiseptics, and lavage of the large bowel.

Dr. **WILLIAM COLLIER** (Oxford) also remarked that more attention might be devoted to the intestinal conditions which preceded appendicitis. He referred to a case which he had recently seen in which operation was delayed with advantage. He doubted whether surgeons saw the early cases of appendicitis attended with mild symptoms which general practitioners met with so largely. He thought that more lives had been saved by early operation than had formerly been lost by delayed operation, but amongst the disadvantages of operation were secondary herniæ and pain in the region of the cicatrix.

Dr. **MICHAEL GEORGE FOSTER** (San Remo) recalled the contention of M. Dieulafoy that membranous colitis rarely lead to appendicitis, but he (Dr. Foster) had watched about 30 cases of the first-named disease and in four of them appendicitis had subsequently developed. Such a high percentage rather favoured the view that it was not uncommon for the morbid process to extend from the colon to the appendix. With regard to the treatment of membranous colitis, he wished to emphasise the value of a large quantity of solid and simple food. Vegetables should always be given in the form of a *purée*.

Dr. R. **SAUNDBY** (Birmingham) referred to a case under his care some years age of relapsing appendicitis which had been operated on in the third attack, the appendix, however, not being removed. The patient died and for some years he (Dr. Saundby) had hesitated to call in a surgeon, but in later years, as knowledge advanced and surgeons become more accustomed to the operation, he had adopted more enlightened views. A patient should not be allowed to go without operation who presented a chronic inflammatory induration in the right iliac fossa or who had repeated relapses.

Dr. W. J. **TYSON** (Folkestone) thought that the subject of the treatment of appendicitis belonged to both physicians and surgeons, but in the early phases of the disease it was undoubtedly medical.

Dr. A. **MCPHEDRAN** (Toronto), referring to the treatment of appendicitis, thought that the application of leeches was a good procedure. The diagnosis was often very difficult and he referred to the value of leucocytosis as an evidence of suppuration.

Mr. C. R. **STRATON** (Wilton) and Dr. **WILLIAM ODELL** (Torquay) also spoke.

Dr. **CHAPMAN** gave a demonstration of the instrument used by him for obtaining simultaneous heart and pulse (index) tracings.

Dr. **WILFRED J. HARRIS** (London) and Mr. V. W. **LOW** (London) made a communication on

The Treatment by Operation of Erb's Palsy, Traumatic Paralysis of the Upper Extremity, and Infantile Paralysis by Cross-union of the Nerve Trunks.

Since Erb in 1874 described in adults the paralysis of the deltoid, the infraspinatus, the biceps, the brachialis anticus, and the supinators, previously described in newly-born children by Duchenne as "obstetrical paralysis," there had always been some uncertainty as to the exact localisation of the lesion. Erb himself first ascribed the condition to a traumatic lesion of the sixth cervical root, but since the experiments of Ferrier and Yeo on the brachial plexus in the monkey in 1883 this form of paralysis has usually been ascribed to a lesion of the combined fifth and sixth trunks. This the authors believed to be an error resulting from an assumption that the brachial plexus of the monkey is identical with that of man. During the last 12 months Dr. Harris had had under treatment two very complete and remarkable cases of this palsy, one traumatic, the other occurring spontaneously, but resembling each other in almost every detail. In each case the paralysis and wasting had been complete, with no attempt at recovery of the deltoid, spinati, teres minor, biceps, brachialis anticus, coracobrachialis, supinatores longus and brevis, pronator radii teres, and extensores carpi radialis longior and brevior. Feeling convinced by previous clinical experience and by a study of the writings of Thorburn and of Sherrington that the sixth cervical root was not involved in these cases, and that the lesion was probably confined to the fifth root, Dr. Harris undertook some dissections and experimental stimulation of the brachial plexus in monkeys and found that it was possible by carefully splitting the roots and following the fibres to the muscles that the spinati, the deltoid, the biceps, and the brachialis anticus and supinator longus were in large part supplied by the fifth root. Experimental stimulation confirmed this result in *rhesus*, and it therefore seemed feasible that an operation might benefit the two patients spoken of by exposing the fifth, sixth, and seventh roots in the neck, isolating and stimulating each faradically, and thereby determining whether one or both of the fifth and sixth roots were affected and if one only to divide it and to sew the distal end of the root into the seventh root in the hope of a down-growth of motor nerves into the paralysed root, similar in plan to the cross-union of nerves for facial paralysis which had been successfully performed. This had been done in both the patients, in one the distal end of the fifth root being sewn into the seventh root, and in the other, the traumatic case, the distal end of the fifth root was sewn into the sixth root. The conditions found at the operations and the results of faradic stimulation of the roots were carefully noted and fully confirmed the opinion that Erb's palsy was due to a lesion of the fifth root alone. In the traumatic case before the operation there were comparative anæsthesia and subjective numbness over the whole of the thumb and the outer side of the index finger, dating from the time of the fall on to the shoulder. This rapidly improved after the operation, disappearing entirely within a week, the improvement being probably due to the sixth root having been freed and cleaned from the scar tissue. No motor improvement had yet occurred in either case, nor was it to be expected for many weeks, six weeks only having elapsed since the first operation. Applying the same reasoning to infantile paralysis (acute anterior poliomyelitis), since it is fully proved that the cord segments corresponded exactly to their respective motor roots, it had occurred to Dr. Harris that an operation on the fifth root might also be beneficial. This was accordingly done in a case of infantile paralysis of four months standing in a little girl, aged two years, the muscles affected being the deltoid and the supra- and infra-spinatus, while the biceps and all the other muscles were normal. At the operation the fifth root was split longitudinally in halves and it was found by faradic stimulation of the two halves separately that the upper half supplied the deltoid, while the biceps was supplied by the lower half. The upper half of the fifth root was then cut across and its distal end turned over and sutured into the sixth root. Uneventful recovery from the operation followed but it was still too early to expect any motor improvement.

Dr. R. **LORD** (London) read a paper entitled "Personal Reflections on the Treatment of Disease by Antitoxins, Toxins, and Vaccines, together with other uses of Serum-therapy."

SURGERY.

WEDNESDAY, JULY 29TH.

A discussion on

Intra-Abdominal Anastomosis

was opened by Mr. G. H. **MAKINS** (London) who commenced by pointing out that statistics based on the earlier records of intestinal anastomosis were at the present time practically valueless and misleading, for so much advance had recently occurred that the results of a few years ago were not to be compared with those obtained at present. He continued: There are three methods of joining intestine—namely, (1) axial or end-to-end, (2) lateral anastomosis, and (3) lateral implantation. Axial anastomosis should be limited to cases where the bowel is invested with a complete peritoneal covering and provided with a free mesentery, so that the intestine can be moved sufficiently to allow the anastomosis to be carried out, while lateral anastomosis is applicable everywhere except at the junction of the sigmoid flexure and rectum. In favour of the axial method it may be said that when it heals thoroughly the result is very good and only one joint has to be made, but against it it may be said that the nutrition of the junction is not good for the vessels have to be divided where they are large and thus the union may not be so firm and the risk of leakage is greater. It is true that in the vast majority of cases in which leakage occurs it is very slight and only gives rise to a little local inflammatory exudation around the junction, but even this would tend to retard recovery. In favour of lateral anastomosis it might be pointed out that this is the "natural" way in which an anastomosis occurs in disease, as in "vicarious communications" between two portions of bowel. The advantages of lateral anastomosis are: (1) that it approximates two plane surfaces of intestine instead of corrugated surfaces as in end-to-end union; (2) the size of the opening can be made as large as is necessary so that there is no risk of cicatricial contraction; (3) it is possible to avoid completely the mesenteric border and thus the intestinal vessels are only divided where they are small; and (4) it is possible to avoid the field of disease without removing too large a portion of bowel as in necrosis of the bowel after strangulation. Moreover, when leakage does occur after lateral anastomosis it is almost always at the blind end of the bowel. Lateral implantation is chiefly applicable to cases where it is desired to unite a piece of bowel of small lumen to one much larger, as in union of the ileum to the ascending colon. Mr. Makins here quoted statistics bearing on these points. At St. Thomas's Hospital the mortality of all the cases of axial union was 53 per cent., but on the other hand Littlewood had performed 11 enterectomies for carcinoma of the large bowel and the death-rate was under 28 per cent. Von Eiselsberg had 12 cases of resection for intussusception and in these cases union was by axial anastomosis and the mortality was 25 per cent. Mr. Makins proceeded: It must not be forgotten that the mere method of uniting the intestine is not the only thing of the greatest importance to preserve the wound free from contamination. This is accomplished by careful clamping of the intestine on each side of the field of operation. I consider that Doyen's is the best intestinal clamp. It is important to determine the amount of mesentery to be removed; this will depend on the cause of the enterectomy. In cases of gangrene the amount of gangrenous bowel determines the amount of mesentery needing removal, but if a new growth is to be excised the degree to which the mesentery is diseased will determine the extent of bowel to be excised. It is best to remove the mesentery first before the bowel is incised. Folding of the mesentery is done most commonly in strangulated bowel but it is not always safe, as the veins may be the seat of a septic thrombosis. Two tiers of sutures should always be employed, the inner including chiefly the mucous membrane and the outer only the serous layer and a portion of the muscular coat. The simpler the method of suture the better and the simple continuous method is the best. Murphy's button is theoretically very good, but the practical objections are great. Oblique section of the bowel has been tried, but where it is sutured there is apt to be a kink. Should any excessive mucous membrane be present it is better to remove it, as it tends to form a "diaphragm."

Mr. E. **Stanmore Bishop** (Manchester) also contributed a paper to the discussion. He commenced by making the suggestion that the portion of the circumference of bowel most distant from the mesentery should be called the "fundal" point or line, agreeably to the analogous use of the word "fundus" in the description of the uterus and bladder. Mr. Bishop's opinion on intestinal anastomosis was founded mainly on 22 cases, most of which were connected with hernia. In one of these cases a portion of gangrenous bowel was excised and the ends were united by a Czerny-Lembert suture, yet a "diaphragm" formed and this becoming œdematous caused fatal obstruction. In Mr. Bishop's opinion the question of the value of mechanical assistance was closely associated with the question of the portion of bowel to be dealt with. If the anastomosis were in the upper part of the small bowel or the stomach the contents were liquid and could exert a dissolving action on a decalcified bone bobbin, but lower down the intestine the contents were more solid and had less dissolving power; therefore absorbable appliances were more suitable in the upper portion of the bowel. Some dough bobbins were shown and bone "couplers" devised by Frank of Chicago were exhibited. Mr. Bishop proceeded to discuss various other mechanical appliances which had been employed for intestinal anastomosis, such as O'Hare, Vidal, and Doyen forceps, and he described other methods of suture. He thought that there was no reason why the inner suture should not perforate the whole thickness of the bowel wall.

Mr. **Jordan Lloyd** (Birmingham) claimed that in intestinal anastomosis simplicity was the most important point; he himself employed common sewing needles and common silk (of course carefully sterilised). He considered that many mechanical appliances were very dangerous. It was true that simple suture took a little more time than the employment of a mechanical appliance but the difference was only slight. It was important that the abdominal wound should be sufficiently large to permit of easy manipulation. In his opinion the chief danger was hæmorrhage. On the whole, lateral anastomosis should always be done when circumstances permitted.

Mr. E. **Deanesly** (Wolverhampton) maintained that lateral anastomosis was not so natural as the end-to-end form, for in those rare cases of intussusception where recovery followed sloughing of the gut the bowel united by axial anastomosis. He approved of the use of two tiers of sutures, the inner going through all the coats. No mechanical appliance need be employed, needles and silk only being required. In every case a "diaphragm" must form, but it only became excessive when too much oft he bowel was turned in.

Mr. R. C. **Elsworth** (Swansea) mentioned that in his last six cases of intestinal anastomosis he had used Murphy's button and all had recovered. He considered that most of the fatal cases in which the button was used were due to the method employed. The parts of the button should be pressed together as firmly as possible and it was as well to add a few external stitches.

Mr. J. **Basil Hall** (Bradford) formerly employed the bone bobbin, but now he used simple suture, the inner suture of catgut, passing through all the coats, and the outer of silk.

Mr. G. G. **Hamilton** (Liverpool) had tried the Murphy button and, indeed, he employed successfully a one and a half button in two cases of colectomy, but now he used nothing but the simple suture.

Mr. **Sinclair White** (Sheffield) considered that by ligaturing the mesentery first he obviated the risk of hæmorrhage. He had had many successful cases of enterostomy in which he employed Murphy's button, but in five of the cases he never saw the button again. He favoured simple continuous suture.

Mr. A. B. **Mitchell** (Belfast) spoke strongly in favour of two tiers of simple continuous suture, the inner one passing through all the coats and the outer through the serous, the muscular, and the submucous coats. In lateral implantation the incision into the bowel should be transverse.

Mr. A. W. **Mayo Robson** (London) declared that he was in favour of union by suture but that he had found much assistance from the support of the bobbins which he had devised. He considered Murphy's button to be distinctly harmful, for the surgeon could never be certain what would happen.

Mr. W. H. **Horrocks** (Bradford) related a case of malignant disease of the bowel in which he removed 36 inches of gut and then invaginated the lower portion of the bowel into the upper and fixed it there with sutures. The case did very well.

Mr. F. F. **Burghard** (London) considered that the "diaphragm" which sometimes appeared after end-to end anastomosis was due to turning in too much of the bowel by means of the external sutures. He thought the material of which the suture was composed to be a matter of very slight importance.

Mr. **Edmund Owen** (the President of the section) expressed the pleasure which he had derived from the discussion. He noticed that no one had spoken of the need of sewing up the triangular interval in the mesentery; he thought that attention to this point was of great importance.

Mr. **Makins** and Mr. **Bishop** replied.

OBSTETRICS AND GYNÆCOLOGY.

Wednesday, July 29th.

Professor W. **Stephenson** (Aberdeen), the President, gave a short introductory address on

The Trend of Opinion in Obstetrics.

He remarked that those whose student days, like his own, dated back 40 years or more, were conscious of great advance in the science, and many changes in the practice, of obstetrics. Gynæcology as a special branch was unknown then. The younger generation of to-day could not realise the wonder which a successful case of ovariotomy then excited or the dread of opening the peritoneal sac. Similarly the use of the forceps was at first contemplated with something like alarm by the generality of the profession. A change of wide influence in the sphere of obstetrics in the present day was the freer acceptance of the principle of interference as contrasted with the opposite principle so strongly inculcated in former days. Such interference was not a question for experts alone; it lay largely within the sphere of the general practitioner. In gynæcology, too, it was essential that the practitioner should have the necessary amount of knowledge which would enable him to recognise the gravity of a given condition and when the services of the specialist should be enlisted. In midwifery in the majority of cases he (the practitioner) himself must also be the operator, for the danger often arose so suddenly and with so little warning that there was no time to summon assistance. This had a decided bearing on the length of time which in the medical curriculum was devoted to the acquisition of such requisite knowledge and also on the methods by which it was sought to impart that knowledge. A deficiency in our text-books was the discussion as to how and when aid should be extended. The mere number of cases attended before presenting himself for examination was no estimate of a man's knowledge of midwifery. Nor yet, on the other hand, should too much reliance be placed on the mere acquaintance with text-books. There was much to be said for the good effect of lectures, systematic and clinical, quickened as they were by the living voice and illumined by the personality and experience of the teacher. His (the speaker's) experience was that the 100 lectures customary in the Scottish Universities were inadequate to overtake the subject, and now in Aberdeen the number of hours was increased by a half more and the time over which the study of the subject extended had been doubled. By means of the cadaver and models the practical study of the anatomy of the pelvic organs, the methods of examination, the mechanism of labour, and the diagnosis of the lie of the fœtal head, as well as the delivery of breech cases and the application of forceps, were all usefully and helpfully studied. Such a class should be made compulsory in all the schools, without of course superseding the attendance on midwifery cases. Whilst in a sense gynæcology and obstetrics were distinct, they had, nevertheless, so much in common and were so wedded together in actual practice that it was not good they should be put asunder. Strictly speaking, in its etymology the term "gynæcology" would include pregnancy and labour. The subjects which would presently be discussed in this section would illustrate the fact that medicine, surgery, and midwifery must all be brought into action in the solution of many of the difficult problems of gynæcology and obstetrics.

Dr. AMAND ROUTH (London) opened a discussion on

The Management of Pregnancy Complicated with Uterine Fibroids.

The object of this discussion was to eliminate methods of treatment which could now safely be abandoned and to indicate the best modern methods. 1. With regard to the effect of pregnancy upon the fibroids, he was of opinion that in those cases where rapid increase of size had been recorded there was nothing to show that it was the fibroid itself which had undergone such increase. Whitridge Williams thought the increase of size was due more to œdema than to actual hypertrophy. Fibroids might diminish in size or even disappear during involution. It was probable that softening during pregnancy must precede absorption afterwards. Playfair in 1877 had recorded a case of almost complete disappearance of a large fibroid which increased again rapidly at the next pregnancy. Intra mural fibroids tended to become driven outwards during involution and become more definitely subserous. Degeneration and extrusion of submucous fibroids might occur after labour, especially if the labour had been prolonged. Such a fibroid might be expelled from the uterus without serious consequences, but usually in process of extrusion the circulation of the fibroid became arrested and sloughing ensued with sapræmia or septicæmia and death if the expulsion of the polyp did not occur. A case illustrating this was quoted in which life might have been saved had hysterectomy been performed when sepsis had declared itself. Fibroids might become infected during the puerperium and the softening effect of pregnancy rendered them most liable to infection. Such an infection at term, though rarer, was more serious than that following abortion. 2. With respect to the effect of fibroids upon a co-existing pregnancy, the question arose as to whether fibroids caused sterility, and in estimating this point it must be remembered that these tumours were most common at an age when pregnancy was naturally less frequent. In reviewing the facts it seemed to him (the speaker) to be probable that fibroids are by no means a frequent cause of sterility and it was possible that Mann's view, that sterility was a cause of fibroid, was truer. Whitridge Williams showed that the sterility is due mainly to endometric changes, to fibroid, or to altered relations of ovaries and Fallopian tubes. Fibroids probably did not predispose to abortion or premature labour, although labour may come on a week or two before full term. A table was shown illustrating this point. Fibromyomata certainly did cause fœtal mal presentation and whilst delay in labour with fibroids was the rule there was no marked tendency to inertia. On the other hand, there was a decided predisposition to post-partum hæmorrhage in these cases and in not a few instances this was due to the association of adherent placenta, which, though sometimes pathological, was most often physiological, and the manual removal necessitated by that condition. A very serious question arose when the physician was consulted at the fourth or fifth month or later as to whether a complicating fibroid would interfere with labour. The fibroid might appear to render the passage of a child at or near term impossible and yet a definite opinion might be formed that the tumour would be lifted up out of the pelvis by the steady growth of the uterus. Mann had recorded a case where such an elevation of the tumour had occurred in the second stage. When this occurred the cervix resumed more or less its normal position. Nature has often succeeded in the removal of an obstruction which repeated attempts by the accoucheur had failed to encompass. Retro-uterine fibroids might become adherent in the floor of the pelvis and become as immovable as intra-ligamentous tumours. Cervical fibroids were the most obstructive of all and, like the intra-ligamentous variety, could not be lifted out of the pubes or pushed up from below. In the puerperium involution was retarded but not impaired. The real danger at this stage was sepsis from decomposition of retained portions of placenta, and this readily affected the fibroids. As regards treatment, if the patient were first seen before fœtal viability and if obstruction appeared probable attempts to elevate the pelvic fibroid might be made by gentle digital or hydrostatic pressure in the Sim's or knee-chest position, forcible attempts being avoided. Failing success an attempt might be made under A.C.E. mi

foot of the bed was a useful

agreed that induction of abortio

be abandoned. This latter proced

were nearly out of reach and even

factorily dilated, the distended uterine cavity rendered complete removal of the placenta difficult. In fact, the easier it was to induce abortion the less necessary was it to interfere at all. Induction then left the woman with a fibroid and did nothing towards enabling her to have a living child in the future. An expectant attitude should be adopted. The existing pregnancy might be the only chance of the woman having a living child and therefore every opportunity should be afforded her of going to full term. Myomectomy before fœtal viability was now the ideal indication when pressure symptoms developed before fœtal viability and it had the advantage that if necessary hysterectomy might be effected. Hysterectomy before fœtal viability was required after incomplete abortion where hæmorrhage or sepsis was present. If the patient were first seen after fœtal viability expectant treatment should here again be adopted if the mother's life were not endangered. Reposition might be tried even up to full term. One thing was certain, a high degree of danger was associated with attempts to deliver by forceps, version, or embryotomy. Vaginal enucleation might be indicated in place of pan-hysterectomy where the fibroid was situated in the cervix. But in all other cases of obstructing fibroid abdominal section should be employed and the child delivered by Cæsarean section. Thereafter a number of procedures presented themselves for differential consideration. To proceed no further than the Cæsarean section would rarely be right. Recorded results did not testify that bilateral oöphorectomy would be followed by atrophy of the fibroid. Myomectomy was sometimes indicated after the Cæsarean section. When abdominal hysterectomy was performed preference should be given to the supra-vaginal operation with retro-peritoneal treatment of the stump by Baer's or Chrobak's methods. If pan-hysterectomy were indicated Doyen's method was the best and one ovary at and forms of administration was shown on the well-arranged stall of Messrs. Wyleys, Limited, of Coventry. Amongst these may be mentioned the non-alcoholic tinctures prepared with a glycerine basis, fluid extracts, antiseptic pellets, hypodermic pellets, gelatin-coated pills, and a non-acid syrup of the glycerophosphates of lime, soda, potash, magnesia, and iron. Amongst the interesting number of preparations shown by Messrs. Burgoyne, Burbidges, and Co. of 12 and 16, Coleman-street, London, E.C., was "salocreol," a combination of salicylic acid with beechwood tar. It is regarded as, in fact, a salicylic ester of creasote which has been found valuable in erysipelas in the face, in chronic and muscular arthritis, and in lymphadenitis. Specimens of lactate of silver, citrate of silver, and colloidal silver were also shown by this firm. Messrs. C. J. Hewlett and Son of 35-42, Charlotte-street, London, E.C., publish an interesting pamphlet on new remedies and special pharmaceutical preparations, specimens of which for the most part were exhibited at their stall. Amongst the drugs exhibited were heroine, lecithin, urea, and phenolphthalein. They showed in addition a number of antiseptic preparations as well as clinical tests for urinary analysis and the apparatus already noticed in our columns which is designed to facilitate the application of Unna's pastes in skin affections. Antiphlogistine was the feature of the stall of the Denver Chemical Manufacturing Company of New York and 110, Cheapside, London, E.C. As we have already pointed out, antiphlogistine is an undoubted advance on the old-fashioned cataplasm. It is a soothing and perfectly clean application. There is a special preparation exhibited by the Charles H. Phillips Chemical Company of 14, Henrietta-street, Covent-garden, London, W.C., which calls for notice. It is milk of magnesia, an emulsion of pure hydrate of magnesia which is specially valuable as an antacid. We have already pointed out its advantage in our analytical columns. Specimens of ovo-lecithin, the definite organic phosphorous compound obtained, amongst other things, from egg, were exhibited by Billon's Ovo-Lecithin Depôt of 16, Water-lane, Great Tower-street, London, E.C. The favourable results which lecithin appears to give in encouraging cell multiplication should draw attention to the value of this organic phosphorous compound in depressed conditions of nutrition. Local pharmacy was very well represented by Messrs. J. T. Davies and Co. of 13 and 14, Walter-road, Swansea, who, in addition to drugs, showed a large assortment of medical and surgical instruments and cotton-wools, lints, and gauze. Messrs. Philip Harris and Co., Limited, of 144 and 146, Edmund-street, Birmingham, presented an interesting series of pharmaceutical preparations to view, while Messrs. Arthur and Co. of 69, Berners-street, London, W., exhibited their well-known compound of gold, arsenic, and bromine known as bromaurum and a number of other preparations which we have noticed on previous occasions. On the whole it may be said that the drug section was not so well represented as in former years; there were certainly fewer novelties. Latterly, the tendency has been in favour of the number of special foods exhibited predominating over the number of drugs, but this year the food section also was not on a very large scale.

II.—FOODS AND FOOD PRODUCTS.

As already mentioned this section was comparatively limited in scope and the absence of the usual variety of milk foods and milk products was noteworthy. Indeed, most of the food products shown were preparations derived from meat. The British Somatose Co. Limited, of 165, Queen Victoria-street, London, E.C., showed their somatose preparations which have already been described in THE LANCET. Mention may be made in particular of liquid somatose which is a powerful nutrient preparation containing 80 per cent. of beef albumin converted into soluble and uncoagulable proteose. The powdered somatose may be used with great advantage as a nourishing adjuvant to all kinds of foods. The preparations of iron-somatose and milk-somatose are also of interest. We have also described in the analytical records from THE LANCET laboratory the preparations of the Myosin Albumin Meat Extract Company of 107, Strand, London, W.C. Thus mamesin is a preparation of pure myosin albumin containing also the extractives of the meat and the iron and phosphorus in organic combination. Mamesin is a direct nutrient. Marmite resembles beef extract very closely as regards appearance and taste, while it contains albumoses although it is an entirely vegetable extract. It has been used as a nutrient with advantage over meat preparations in gouty and rheumatic conditions. Specimens were shown by the Marmite Food Extract Company, Limited, of 40, Mincing-lane, London, E.C. Vegox, on the other hand, is an extract prepared from both vegetables and beef by Vegox, Limited, of 53, New Broad-street, London, E.C. As we have already pointed out in our analytical columns, Vegox is a highly concentrated preparation of nourishing value and possesses an appetising flavour. Messrs. Cosenza and Co. of 95, Wigmore-street, Cavendish-square, London, W., exhibited Maggi's well-known soups. These included the consommé and tonic bouillon contained in a clear solidified form in capsules, and the "Cross Star" soups which were supplied in large quantities to the troops in South Africa. The Liebig's Extract of Meat Co., Limited, of 4, Lloyd's-avenue, London, E.C., showed specimens of their well-known extract, lemco, as well as oxo, their fluid beef. The latter contains meat fibre as well as the albumins and extractives of beef. A very large assortment of specialities for invalids was exhibited by Messrs. Brand and Co., Limited, of 11, Little Stanhope-street, Mayfair, London, W. Attention may be directed in particular to their nutrient powder and their fever food which is a palatable jelly prepared from beef, eggs, and cream. Bovril, Limited, of 152 to 166, Old street, City-road, London, E.C., exhibited a large number of foods for invalid and for general use. Amongst these were a number of special rations, besides the many series of food containing bovril. On the same stall were shown specimens of virol which contains an active malt extract associated with red bone marrow, eggs, and lemon juice. We have already alluded to the peculiar value of virol as a reparative. The Aylesbury Dairy Company, Limited, of St. Petersburgh-place, Bayswater, London, W., were the only large milk company represented. They showed specimens of humanised milk, peptonised milk, sterilised milk, and many other milk preparations. Condensed milk was represented by one firm, that of Mr. Henri Nestlé of 48, Cannon-street, London, E.C. Amongst the preparations shown were condensed Swiss milk containing the whole of the cream and a special food for infants and invalids. Messrs. Callard and Co. of 65, Regent-street, London, W., exhibited their starchless and sugarless foods designed chiefly for sufferers from diabetes and obesity. Mention should also be made of the breads and biscuits enriched with casein and of the sugarless marmalade, chocolate, jellies, and starchless flours. There were many interesting food preparations designed for the use of the diabetic and the dyspeptic on the stall of the Cheltine Foods Company, Limited, of Cheltenham. The exhibits included an infants' food, soluble maltose food, and malted milk chocolate. Maltova is an undoubtedly valuable food, consisting of a combination of fresh eggs with malt extract. The preparation was exhibited by Maltova, Limited, of Leeds and London. The preparation has been dealt with in THE LANCET laboratory. Messrs. J. van Abbott and Sons of Baden-place, Crosby-row, Borough, London, S.E., exhibited their well-known food preparations for diabetic patients. We may, in particular, commend the midolia biscuit which has the advantage of being cheap, while its composition is adapted for special requirements. The exhibit included gluten bread and biscuits, soya biscuits, and almond flour. Mellin's Food, Limited, of Stafford-street, Peckham, London, S.E., exhibited their well-known malted food, besides some biscuits and chocolate. Messrs. Broomfield and Co. of 83, Upper Thames-street, London, E C., exhibited a highly refined vegetable fat called albene, which is recommended for cooking and baking purposes in the place of lard, margarine, and butter. It has the advantage of keeping sweet and does not get rancid. The shredded whole-wheat biscuit and "triscuit" are well known as entire cooked preparations of the wheat berry, showing on analysis a maximum proportion of the nourishing constituents of wheat. These preparations were exhibited by the Shredded Wheat Company of 6 and 8, Eastcheap, London, E.C. Patent groats and patent barley were the subjects of exhibition by Messrs. Keen, Robinson, and Co., Limited, of Garlick-hill, London, E.C. The former is admirable for making a nourishing gruel and the latter, as is well known, serves excellently for diluting cow's milk for infants' use. The only cocoa represented was that of Messrs. Cadbury Brothers of Bournville near Birmingham. As our analysis has shown, Cadbury's cocoa is not manipulated with alkali or alkaline salts. It yields, in particular, an amount of mineral matter consistent with an absolutely pure cocoa deprived of the greater part of its fat.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the July sittings of the Scottish Conjoint Medical Board in Glasgow the following candidates passed the respective examinations.—

Beveridge M'Gregor, Anderson's

course)—Robert Roberts, William
Vallen Strickland, Glasgow School
ge, Belfast, and John Cretin, Uni

William Bruce, M A., M D, LL D, Dingwall

THE JENNER INSTITUTE OF PREVENTIVE MEDICINE—An extraordinary general meeting of the members of the Jenner Institute of Preventive Medicine was held on July 22nd in the board room of the institute, Chelsea-bridge road, to consider a motion to alter the name of the institute to "The Lister Institute of Preventive Medicine." Sir Henry Roscoe occupied the chair and in moving the proposal said that out of motives of delicacy, which they all appreciated, Lord Lister, the chairman of the institute, had not attended the meeting Sir Henry Roscoe read extracts from the memorandum which explained the reasons that had induced the governing body to propose the change of name, and said members would be glad to know that the name proposed had met with the full approval of Lord Iveagh who had been such a munificent donor to the institute He was sure that all present would agree that they could not have a name which was more consonant with the feelings of those who were interested in the progress of preventive medicine than that of the Lister Institute. He thought it would be approved not only by the members present but by all the members and also by the medical profession generally and the public at large. Sir Joseph Fayrer, in seconding the motion, said he had never before seconded a motion with greater pleasure. He did not think it possible to have a more appropriate name than the one proposed. Dr W. J Simpson supported the motion which was unanimously adopted. A second meeting will be held on Friday, August 7th, when the resolution will be submitted for confirmation.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—On Saturday, July 18th, the annual distribution of prizes was held in the board room of the hospital, in the presence of a large gathering of the students and their friends, the members of the staff, and governors of the hospital. Mrs.

DETERIORATION OF MICROSCOPE LENSES AND INDIA-RUBBER GOODS IN HOT CLIMATES.

THE following is from a paper on the Preservation of Instruments in Bengal, read by Mr. Paul Bruhl before the Calcutta section of the Institution of Electrical Engineers on March 27th and printed in the London *Engineer* of July 24th.

One of the most powerful corroding agents employed by nature is carbonic acid. We are accustomed to look at carbonic acid as a weak acid ...... but when the acid is more concentrated under the action of high pressures the action is markedly different. Now capillary action has a similar effect on concentration as a large increase of superincumbent pressure; and the carbonic acid present in the film of moisture which covers all articles during the rainy season, or in the film separating two surfaces in apparent contact, is in a much more concentrated state than corresponds to the atmospheric pressure. Such carbonic acid is capable of displacing the silicic acid of natural and artificial silicates. ...... Microscopists know how difficult it is to keep a stock of blank glass slides. If you keep your glass slides in contact with each other they are sure to grow dim ...... sometimes even if placed in alcohol. An absolutely safe plan is to tie two threads round each separate slide near its two ends, form a number of slides into bundles and keep them in alcohol or formalene. ...... The worst place to keep microscope objectives in during the rainy season is the cylindrical brass case provided for them by the makers. Microscope lenses, in fact lenses and glass parts in general, do not stand close confinement for any length of time. Constant use is the best preservative. In any case place the lenses in a capacious box and air them frequently. ...... Some of the modern kinds of glass have to be tended very carefully ...... otherwise they will soon become dim evenly all over their surface. ...... The best way of keeping rubber stoppers is to put them into a wide stoppered glass jar, at the bottom of which is placed an inverted perforated dish to serve as a support for the stoppers after pouring some oil of turpentine on the bottom of the jar. Stoppers which have acquired a hard cracked surface can be softened by proceeding similarly, only using chloroform instead of turpentine. A good way of preserving rubber tubing is to give it a coating of glycerine.

ORGANO-THERAPY.

DR. MARPMANN of the Hygienic Laboratory in Leipsic has sent us an account of some unexpected results which have been obtained in that institution with the root of an Indian plant. When various extracts and other preparations of this root, the name of which he has written very indistinctly, were administered to the human subject, even in very small doses, they produced a transient sedative effect, followed by pain in the stomach and violent headache. Rabbits, weighing three or four pounds, were killed in four hours by the subcutaneous injection of 0·1 milligramme of the ethereal extract of the root. When, however, injections of 0·01 milligramme were given and continued in increasing doses for ten days such toleration was established that the rabbit was unaffected by injections of one milligramme and upwards, quantities which, if given at first, would certainly have been fatal. From these rabbits thus "immunised" it was found that a substance could be prepared which was useful in the treatment of neurasthenia while possessing the toxic qualities of the root in only a slight degree and none of its disagreeable after-effects. An addendum to Dr. Marpmann's communication states that it has been found possible by passing arsenical compounds through the bodies of animals to produce "organo-preparations" in which, although they contain arsenic, the ordinary physiological effect of that element is materially modified.

THE ADMINISTRATION OF CALCIUM CHLORIDE.

To the Editors of THE LANCET.

SIRS,—Your correspondent "Z" will find that the liquid extract of liquorice root or peppermint water and simple syrup most effectually disguise the taste of calcium chloride. One hour after a meal is the best time for administration, or the drug may be given by means of enemata as used by Gross in quantities of 200 cubic centimetres (six and two-third fluid ounces) of an aqueous 5 per cent. solution. Mr. A. W. Mayo Robson, in THE LANCET of April 12th, 1902, p. 1024, mentions that he gives as much as 60 grains three times a day by the rectum.

I am, Sirs, yours faithfully,
July 28th, 1903. W.

KEYMER BRICK AND TILE COMPANY, LIMITED: A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of July 25th, p. 257, you publish a judgment by Mr. Justice Joyce granting an injunction against the above company for creating a public nuisance. As several medical men and friends have read this notice as referring to my estate, Coombe Hill, Sussex, I should be much obliged if you would be kind enough to publish this disclaimer, as otherwise it is calculated to do my property and myself serious injury.

I am, Sirs, yours faithfully,
Coombe Hill, Sussex, July 28th, 1903. W. E. KEYMER.

THE RAINFALL OF JUNE, 1903.

THE remarkable rainfall of last June, which caused much inconvenience and damage by flooding in the Thames Valley, is the subject of a detailed analysis in the July number of *Symons's Meteorological Magazine* (published by Edward Stanford, Long-acre, London, W.C.). During that month the rainfall was very unequally distributed over the British Isles, the wettest part having been the south of England and the driest part the north of Ireland. A broad, dry belt in which the fall scarcely anywhere reached two inches (and nowhere reached the average for the month) stretched from North Wales and the Mersey to the Humber and the Wash, separating a slightly higher rainfall on the north from an excessively high rainfall on the south. The wet zone stretched from west to east across the country. Along the axis of it from Swindon to Southend, for a distance of 110 miles, the rainfall exceeded six inches, being more than three times the average amount. This extremely heavy fall prevailed over the greater part of the valley of the Thames and the Lee; in the south, especially in the neighbourhood of Croydon, it exceeded seven inches and at Carshalton it reached the unprecedented figure of 8·91 inches. It is estimated that in the ten days between June 8th and 19th, during which all the rain fell, the amount of water deposited on the drainage area of the two rivers, the Thames and the Lee, was 1,494,000,000 tons, or 334,560,000,000 gallons. One inch of rain over one square mile of area is equal to about 64,660 tons of water, or 14,483,000 gallons. Observations made at Camden-square in London showed that rain to the depth of 6·43 inches (which was the whole of the month's rain) fell in those ten days, and on the assumption that this rate held good for the whole metropolitan county the amount of water deposited in London during the period when it was falling averaged 433,000 tons, or 97,000,000 gallons, per hour. This total of 6·43 inches for the month of June has only been exceeded in June, 1878—with 6·71 inches, and only on one other occasion in any month—namely, in August, 1878, with 6·72 inches.

ASTROLOGY.

To the Editors of THE LANCET.

SIRS,—Your readers may be interested to learn that belief in astrology is not yet extinct in Norfolk. A little time ago I was called in to see a patient who was suffering from an advanced cancer of the parotid gland, from which he has recently died. This patient before seeing me had consulted a quack at North Elmham because he "cured diseases by the stars." After taking his money this "cunning man" told him the tumour could be cured, but that in order to cure it he should need to know "what star the patient was born under." The poor old man went away sorrowful as he could not supply the necessary information and he died under the impression that the disease was curable if only the demands of the quack could have been met.

I am, Sirs, yours truly,
Fakenham, July 28th, 1903. F. L. POCHIN, M.B., C.M. Edin.

PROTRUSION OF THE NAVEL.

To the Editors of THE LANCET.

SIRS,—I should be obliged for any hints in regard to the treatment of an abnormally protruding navel in a boy, aged three months. I have tried simple pressure without success.

I am, Sirs, yours faithfully,
July 28th, 1903. RAMUS.

◆

S.W.—We are sorry to be unable to refer our correspondent to any book or journal which describes the operation in question. There is no doubt that the skin does absorb oils and fats if applied by rubbing, and the most obvious proof of this is the old-fashioned method of giving mercury by inunction. The absorption of the mercury was soon apparent and as the drug was intimately mixed with the fat the presumption is that the fat was absorbed also. There are various preparations of iodine dissolved in fatty substances which if rubbed on the skin rapidly disappear, when iodine can be detected in the urine and the taste of the drug can be perceived in the mouth.

Ethical.—The paragraph is an unfortunate one, but there is no reason to suppose that the medical man in question is in any way responsible for its insertion.

L.R.C.P. & S.—We think if our correspondent wrote to the secretary of the Jenner Institute of Preventive Medicine that he would obtain the information which he requires.

M.R.C.S.—The preparation in question is, we believe, an organic compound of bromin.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Yorkshire Post, Yorkshire Daily Observer, Staffordshire Sentinel, Times of India, Aberdeen Free Press, Pioneer Mail (India), Dublin Evening Telegraph, Echo, Bradford Observer, Daily Express, Globe, Medical Brief (St. Louis, U.S.A.), Knowledge, Westminster Gazette, Windsor and Eton Express, Derbyshire Courier, Derbyshire Times, Reading Mercury, Herts Advertiser, Daily Telegraph, Manchester Weekly Chronicle, &c.*

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1903, which was completed with the issue of June 27th, and the Title-page to the Volume, were given in THE LANCET of July 4th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1903 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently *inquiries concerning missing copies, &c., should be sent to* the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

important provision and one likely to promote the cure of the patient and to prevent him from leaving the institution before he has given the treatment a fair trial. If the sum paid to the relatives is insufficient the insurance institution by its influence with charitable organisations is able to augment the allowance. The duties of the insurance authorities extend to endeavours to procure suitable employment for those who are leaving the sanatorium and among the rules connected with one of the insurance institutions is the following: "At least three weeks before dismissal from the sanatorium every patient has to request the inspector of the institution to apply for work at the appropriate place. It is the purpose of the sanatorium to restore the capability for work and it is necessary to make use of this capability at once on the return home so that the absence of means for maintenance and the want that would follow do not cause the advantage to be lost which has been gained by a successful cure at the sanatorium." There is only one more point with which I need trouble you, but it is an important one. The insurance institutions invest their surplus capital in a manner to promote the health of the worker by, among other things, lending at a low rate of interest money for building workmen's dwellings. In this sense the insurance force seems to me to be performing an admirable preventive work.

As to the influence of this insurance system upon the health of the people I will quote the following passages from a German report: "The three branches of the German National Workmen's Insurance—the sickness, accident, and invalidity insurance—supplementing one another mutually, form a complete organisation and have resulted in the formation of a new working man's code which in the inevitable fluctuations of modern industrial life will afford to all those in need of assistance a welcome aid and in its further development cannot fail to exercise a great and salutary influence on the economical and social conditions of the working people—indeed, on the entire nation." As regards the improved social condition which I wish here more particularly to accentuate I would draw attention to one more passage from the German work to which I have already referred: "It is comprehensible that workmen's insurance with its far-branching institutions and performances, must affect public life in many ways. Through it the legal condition of the workman is raised to a higher standpoint. In place of the former almsgiving the workman has now a claim on sick relief and pension. The social condition of the workman is advanced by the assurance of relief which extends itself also over the family in case of sickness, incapacity from work, or death. In spite of the burden cast upon the employer through workmen's insurances wages have advanced and production has increased in the German Empire. …… The workmen's insurance has also done much in furthering the hygienic conditions of the working people. By the circumstance that, in cases of sickness and incapacity from work, indemnity is to be paid the endeavours to avoid and prevent dangers of sickness and accident receive not only a moral but also a financial impetus. That the health of the workman is guarded or restored as soon as possible lies in the common interest of the managing boards of the sick clubs, of the Employers' Association, and of single employers, whose zeal for social reform is furthered by the insurance institutions on the one side and of the workmen themselves on the other. The consequence is that more and more is being done for better and more thorough cure. *The working people receive more and more care from the physician.*" (The italics are mine.) Since that date there are signs in this country that a more hopeful view may ere long be taken and I see that Dr. A. P. Hillier, the secretary of the National Association for the Prevention of Consumption, has recently taken to Berlin a deputation from the friendly societies of this country in order that they might see for themselves the advantages of the German methods and determine to what extent they are practicable in England.

It has to be borne in mind that the insurance system in Germany is dependent upon the united efforts of the employed, the employer, and the State. The matter is largely a social and political one and must be decided upon those grounds, but I have dealt with it here at some length because, in common with Sir John Burdon Sanderson,[2] I feel that in this compulsory insurance against invalidity the Germans have a system the value of which it is difficult to over-estimate, and I say this, not because this system aids so materially the erection and maintenance of sanatoriums, but because the material benefits which the insurance system provides in ill-health of all descriptions must obviously improve the resistance of the host against the onslaught of the tubercle bacillus. As an illustration of my point I would add that by the provisions of the Acts in question it is enacted that when it is feared incapacity for work may ensue, medical treatment is granted with a view to *preventing* disablements. This is preventive medicine properly understood. This workman's insurance system in Germany, as I have already said, was initiated by the Emperor William I. in 1881.

At the time of the British Congress in 1901 the honorary secretaries of the State section endeavoured to awaken the interest of English insurance and friendly societies in this matter. They were able to procure a valuable contribution from Mr. E. W. Brabrook, C.B., chief registrar of the friendly societies in this country, and an exhaustive essay from Mr. Hoffman, statistician to the Prudential Insurance Company of America. Both these gentlemen naturally approached the problem in a purely critical spirit and the conclusion at which they independently arrived was that it was not in the interests of either insurance societies or friendly societies to contribute towards the erection or maintenance of sanatoriums.

The progress of the movement for the erection of sanatoriums in Germany has been altogether remarkable. Professor von Leyden, speaking in the name of the German empire at the British Congress in 1901, stated that there were 22 sanatoriums in 1899, 39 in 1900, and 59 in 1901. From an interesting account given by Dr. Pannwitz in the June (1902) number of the German periodical *Tuberculosis* it would appear that in the spring of 1902 there were no fewer than 89 public sanatoriums either in existence or in process of being erected. This total is exclusive of the 20 private sanatoriums which were then in existence in Germany. As we have already seen no fewer than 37,000 patients were treated in these sanatoriums in 1901.

FRANCE.

Briefly summed up, the principle which the French have endeavoured to apply better than any other nation is that of the early recognition of the disease by the establishment of the anti-tuberculous dispensaries. France has recognised that it is at present impracticable to provide sanatoriums for the whole of the 400,000 to 500,000 tuberculous persons believed to exist in the Republic and has appreciated, too, that, even were this practicable, the detection and prevention of tuberculosis, as well as the treatment of patients discharged from sanatoriums, would still be an essential portion of the scheme in its entirety. It was this belief that led Professor Calmette, Professor Landouzy, and Professor Letulle to lay down at the British Congress on Tuberculosis the following expression of opinion: "We wish, without in any way prejudicing the rôle which the sanatorium must play in the battle against consumption, to urge upon governments, local sanitary authorities, Poor-law authorities, and charity organisations the *necessity* of encouraging the institution of anti-tuberculous dispensaries as the best means of struggling against tuberculosis in the working classes." The idea of these institutions appears, as far as I can ascertain, to have originated with Dr. Bonnet-Léon, and it was brought before the French Commission on Tuberculosis by Professor Calmette, director of the Pasteur Institute at Lille. Professor Calmette gave an excellent account of the operations of the dispensary inaugurated at Lille in the Transactions of the British Congress. Shortly stated, the object of this and kindred institutions is to educate the public in hygiene and to afford assistance to the poorer workmen who are suffering from tuberculosis. In Professor Calmette's opinion dispensaries of this nature should *precede* and *complete* the foundation of sanatoriums. In the first instance they afford an opportunity for selecting suitable patients for sanatoriums and in the second they offer facilities for carrying out after-treatment of those who have already sojourned in sanatoriums. Belgium has also developed this dispensary idea to a very high degree. The example set by Dr. Bonnet-Léon and Professor Calmette has been followed by others and a society has been founded in Paris with the object of furthering the development of such institutions, while at Arras and Nantes similar institutions are in course of construction.

There are now in France several sanatoriums of a private character. There is at Angicourt (Oise) a sanatorium for the [illegible] sanatoriums either erected [illegible] poor of other places, such as [illegible] e also several hospitals for [illegible] to those at d'Ormesson and Villiers-sur-Marne, both of which have agricultural colonies *connected with them.*

---

[2] Our Duty to the Consumptive Bread-earner, Brit. Med. Jour., July 6th, 1901.

NORWAY.

As explained in my last lecture I am anxious to bring to your notice the conditions as regards Norway because the death-rate from phthisis in that country shows no sign of diminution. It is probably owing to this fact that the Legislature has determined to attempt to grasp the problem by a series of special enactments directed against the disease. By the Act which came into operation at the beginning of 1901 it is obligatory to notify to the medical officer of health (1) pulmonary or laryngeal tuberculosis attended with tuberculous expectoration; (2) fistulæ in the bones, the joints, or the glands which the physician regards as being of a tuberculous nature; (3) lupus, if attended with discharge; (4) tuberculous affections of the alimentary canal or of the urinary system provided that the tubercle bacillus had been demonstrated; and (5) death due to tuberculous disease such as the above or change of abode in similar circumstances. The information conveyed by this means to the medical officer of health must be regarded by him as absolutely confidential. Notification may, at the option of the local sanitary authority and with the consent of the State, be imposed upon the consumptive person each time the abode is changed. It is the duty of the attending physician to insist upon cleanliness in the house of the patient and if he be unable to effect this the duty devolves upon the medical officer of health who, if necessary, can order the removal of the patient to hospital; husbands and wives may not be separated. The medical officer of health may forbid tuberculous persons from taking part in the preparation or sale of food-stuffs and forbid tuberculous females from acting as nurses or attendants on children. I am informed by Dr. Holmboe, the director of the medical service of Norway, that in the carrying-out of the foregoing regulations no serious friction has arisen, but he adds that it is but very rarely that patients are sent to a hospital against their will. The right was exercised in Christiania in only four cases in 1901.

The Norway regulations are, so far as I am aware, the most comprehensive of any in existence and we shall all watch with interest their effect upon the behaviour of tuberculosis in Norway. As regards sanatoriums Dr. Hölmboe tells me that at present there are only two such institutions for the poorer classes, but for *isolation* proper as opposed to *cure* use is made of the general hospitals or of institutions erected for the purpose of isolating the tuberculous sick who are a danger to the community.

I am afraid that I shall be unable in this lecture to deal as I had intended with Denmark, Austria, and Hungary, and I must therefore pass on to consider what is being done in

ENGLAND.

I propose now to consider what is actually being carried out or contemplated in England with regard to the control of pulmonary tuberculosis, and in the first place let us look at the prevalence of the disease in this country. Dr. J. F. W. Tatham tells us that, with a few trifling exceptions, there has been during the last 50 years a decrease in the mortality ascribed to phthisis at every age period and in both sexes, but that the rate has varied widely and has been much greater in the female than in the male sex. The figures must, he warns us, be taken for what they are worth and he thinks that the decrease may not be wholly real. Better diagnosis and improved nomenclature may account for some of the decline. The greatest incidence of the disease is at present at the age period of from 45 to 55 years for males and from 35 to 45 years for females and in this sense there has been a material shifting of age incidence since the period from 1851 to 1860. In the year 1900 there were in England 42,987 deaths from pulmonary tuberculosis.

Assuming, as has been generally done, that a phthisical patient lives on an average three years there are likely to be about 120,000 persons suffering from pulmonary tuberculosis at the present time. But the record of the post-mortem room tends to show how very fallacious these figures are likely to be. Professor Clifford Allbutt in an address which he gave at the London Congress put this aspect of the question in a telling fashion when he said, "I am guilty of no extravagance when I suggest that one-third of you who hear me, wittingly or unwittingly, are or have been infected with tubercle. Some of us, ailing indefinitely, may have been the innocent means of infection to others, so secretly stalks infection in our midst"

What is the machinery in operation for ascertaining the whereabouts of both the recognised and unrecognised cases?

Notification.—The number of urban and rural district councils which are adopting the voluntary notification of pulmonary tuberculosis is steadily increasing, but unfortunately it is very difficult to ascertain the precise number. Assuming, however, no check is given to the progress by the production of a logical reaction against extreme measures the near future may see a very considerable adoption of voluntary notification. It cannot, however, be denied that in some places there is a distinct disinclination on the part of the medical practitioner to notify owing to the ban under which such notification may perhaps place the patient. The future, in my view, depends very largely upon the discretion with which the knowledge acquired by notification is utilised. Such pioneers in the movement as Dr. J Niven of Manchester and Dr. A. Newsholme of Brighton [illegible]nistration of [illegible] if their admi[illegible]ell. Logically, notification is no doubt necessary, if by the means proposed we are to "stamp out," as it is called, the disease, but unfortunately the post-mortem records show us that in addition to the notified cases we must still have a considerable number of unnotified cases potent for harm; and we have to bear in mind that the attempt to establish a leper class is not unlikely to lead to an uncertain amount of concealment of active tuberculosis. These considerations raise the important point as to whether pulmonary tuberculosis *shall be compulsorily notifiable.*

If such compulsory notification renders it necessary to subject those suffering from the disease to all or many of the disabilities under the Public Health Acts to which those who are suffering from the acute infectious diseases are legally liable, there can, I think, be little doubt but that the answer *to the question* is in the direct negative. Were it otherwise, a patient suffering from pulmonary tuberculosis would be constantly traversing the statutes when he ventured outside his own door or entered any public institution or conveyance. Assuming, however, that the disease is placed, as I have advocated, *in an entirely separate category* from the group in which what are called the acute exanthemata are ranged and that the information obtained by notification is discreetly used, there would seem to be no very great difficulty in the way of a modified form of obligatory notification; for instance, it might be well to have compulsory notification of pulmonary tuberculosis in the case of patients occupying tenement houses or other places where the first principles of cleanliness are not observed and where the people live much in common with tendency to overcrowding.

I have very grave doubts as to whether it is desirable even in regard to voluntary notification to include any forms of tuberculosis other than pulmonary; it might, I think, in the first instance, be well to limit notification to cases of pulmonary tuberculosis in which the condition and environment of the patient are such that danger to the public is liable to accrue. As to this, I may again quote Professor Koch who, when referring to the subject of notification, said: "Fortunately it is not at all necessary to notify all cases of tuberculosis, nor even all cases of consumption, but *only those that owing to their domestic* conditions are sources of danger to the people about them." There is, I think, much to be said for this view. For the [illegible] the *relative* nature of the problem. I agree, in fact, with the motion which was proposed at the Congress in London by Dr. Newsholme and which in the form in which it was eventually carried stood thus:—

> That the voluntary notification of phthisis attended with tuberculous expectoration, and the increased *preventive* action which it has rendered practicable, have been attended by a promising measure of success, and that the extension of such notification should be encouraged in all districts in which efficient sanitary administration renders it practicable to adopt the consequential measures.

If compulsory notification is to be attempted it should, I think, take the form of a period of trial, say for five years, in one of our large towns, and I have been interested to hear that the corporation of Sheffield, acting no doubt under the advice of Dr. John Robertson, its medical officer of health, has now (August, 1903) a Bill before Parliament which embodies a clause providing for the compulsory notification of pulmonary tuberculosis. If this Bill with the clause referred to receives Parliamentary sanction an interesting experiment will have been set going in Sheffield. The clause in question gives power to the officials of the corporation to enter any house in which there is a patient suffering from pulmonary tuberculosis and to perform any necessary disinfection or cleansing. I am interested to note that the clause relates to pulmonary tuberculosis only and that "no provisions contained in any general or local Act of Parliament relating to infectious disease shall apply to tuberculosis of the lung or proceedings relating thereto under this section." This means that the disease is placed, as I suggested in my first lecture, in an entirely separate category. The information derived from notification is, I understand, to be treated as absolutely confidential and the necessity for the rigid observance of such secrecy seems to be accentuated more and more every day as one reads that in certain places outside of England it is an offence against the law to entertain in one's house a tuberculous subject who is not a relative.

Facilities for bacteriological examination.—If we are to determine early and with accuracy the existence of cases of pulmonary tuberculosis, and as to the importance of early recognition both for the sake of the patient and the public there can be no doubt, it is desirable that every facility shall be afforded to the members of the medical profession to obtain the trustworthy examination of suspected sputum without delay and without expense. The busy medical practitioner can ill afford the time to make such examinations himself and furthermore he has not the opportunities for keeping himself in touch with current bacteriology. Moreover, the necessity for facilities for bacteriological examinations and for serum reactions is urgently obvious in respect of acute diseases such as diphtheria and enteric fever, and hence there is need for numerous well-equipped and conveniently situated laboratories in which such examinations can be made.

Fortunately provisions of this nature are being rapidly made and appreciated throughout the country, and although I cannot pass in review anything that is being done I may perhaps in regard to the provinces make mention of the admirable work that is being carried out at the Thompson-Yates Laboratory at Liverpool, at Owens College, Manchester, and at Birmingham, Bristol, Cardiff, and other places. I may also, while of course recognising the work that is being done by many of our large towns, refer to the progress which is being made in this direction by certain of our county councils by those, that is to say, who have appointed medical officers of health. In certain counties there is now a complete organisation by which every medical man in the county may without trouble or expense procure bacteriological examination or serum reaction. But as regards this question of bacteriological examination I would point out that it is in no sense scientific preventive medicine to wait until tubercle bacilli can be detected in the sputum; by that time the disease may have obtained a very considerable foothold on the patient. The essence of preventive medicine as early as possible is to secure the patient more particularly with regard to pulmonary tuberculosis. This can only be done by educating the public in the enormous importance of seeking medical assistance on the first indication of illness, or better still, by encouraging a condition of affairs by which they shall submit themselves to a periodical and thorough physical examination at the hands of their general medical practitioner. As Dr. Knopf remarks, "We cannot solve the tuberculosis problem without a family practitioner." This is the preventive medicine of the future. In the meantime we must look to our sanitary authorities, our hospitals, dispensaries, and other public institutions to use their influence in this direction. Insurance and friendly societies might also do much good work in this particular, and I am interested to see in the last annual report of the National Association for the Prevention of Consumption that arrangements have been made to furnish certain of these bodies with the necessary popular literature.

But in this matter of what is called the education of the people may I utter a note of warning? It is better to be ignorant than to possess fiction in place of fact, and it cannot, I think, be denied that in connexion with this subject of tuberculosis there is much fiction of a very dangerous nature and such that is likely to harass very materially sanitary administration generally. Since my last lecture Dr. E. C. Seaton has been good enough to bring to my notice an admirable example of a medical lecturer straining rather after effect than accuracy. The lecturer is reported to have stated "that every case of consumption was as much a case of infection as small-pox and scarlet fever. If that were the case and they were able to put their finger upon small-pox and stop it, they ought also to be able to put their finger upon consumption and stop it." The same lecturer added that consumption killed 140,000 people annually in England and Wales. The Registrar-General's annual report for 1900 gives the deaths from pulmonary tuberculosis for that year at *42,987!*

The education and examination of school children.—Of all the means which I have as yet discussed none seem to me to touch in importance that to be attached to the teaching of the laws of health in the private and public schools of this country. I find difficulty in understanding the position of those whose view it is that anything that is being done to-day or to-morrow will result forthwith, or even in the immediate future, in the "stamping out" of tuberculosis. There is no parallel for such an expectation in the history of epidemiology, certainly when the extensive presence of tuberculosis as revealed by post-mortem examinations is held in view.

A very large amount of good may, it seems to me, be done by the education in elementary hygiene and by the periodical and thorough examination of the children in our public schools. I would have the children taught the vast importance, in relation to the tuberculosis problem and to health generally, of fresh air, abundant light, plenty of cubic space per person, and cleanliness; the older children might be shown models of good and bad houses and taught the manner in which houses, huddled together on a limited space, obstruct air and light. I would, moreover, have the children periodically examined, not only as regards the condition of their lungs, but as to their general physical progress and the state of their special senses. Well-regulated physical exercises performed in moderation would also be of value. In this way we should, in my view, be doing a work which would produce results long before the children themselves became householders. Not only would measures such as these tend to prevent and to cure all tuberculous diseases, but they would also have an effect on all other diseases dependent upon diminished resistance, dirt, overcrowding, and absence of light; they would reduce, too, physical infirmities and defects of the special senses.

The Minister of Public Instruction in France, after seeing the report of a commission which he had appointed to examine into the question of tuberculosis in schools, formulated certain regulations which comprised among other things the following. 1. All schools are to be so constructed as to secure abundant light and air and the walls and floors are to be composed of impervious and easily washable material. 2. Each pupil in a boarding-school is to be provided with a card setting forth his or her weight and chest measurements and a revision of such data is to take place every three months.

I am glad to find that Sir James Crichton Browne is bringing the weight of his authority and eloquence to bear in this direction. In a recent presidential address, delivered before the medical section of the International Congress for the Welfare and Protection of Children, he stated that "under-weight is at all early ages common and the most frequent sign of insufficient feeding, malnutrition, and incipient tuberculosis, and I do not doubt that the periodical measurement of children would very often, by disclosing a check in growth or a marked deviation from the normal proportion between height and weight, lead to the detection of the disease still undeclared by any outward symptom and therefore in that stage most amenable to treatment."

I have some hope that the near future may see an advance in this matter of the examination of school children. The county councils which have recently been intrusted with the administration of the Education Acts have here an admirable opportunity of showing initiative and if they properly appreciate their opportunities they will begin with the periodical, say fortnightly, examination of the children under their care. In this connexion I am glad to note that the recent report of the Royal Commission on Physical

Training (Scotland) has recommended *inter alia* a medical inspection such as is here suggested.

Fortunately, the transmission of tuberculosis by direct inheritance is so rare that the circumstances need not enter into practical politics. But children are born tuberculisable though not tuberculous and we are interested in preventing, so far as possible, the hereditary proclivity towards the disease. In endeavouring to do this we need not take quite such a broad evolutionary view of preventive medicine as was taken by Oliver Wendell Holmes when he said: "There are people who think that everything may be done if the doer, be he educator or physician, be only called in season. No doubt; but in season would often be a hundred or two years before the child was born and people never send so early as that."

The control of expectoration.—The importance of the proper control of sputum in limiting the spread not only of tuberculosis but of all other diseases in which the active agent may be contained in the sputum or saliva cannot, I think, be doubted, and for this reason all those interested in the prevention of communicable diseases must welcome any step likely to control promiscuous expectoration. As a matter of actual fact, the habit is very largely a class practice and the remedy of equalising the classes in this particular should not be difficult of attainment. One has only to compare the floor of a third-class with a first-class smoking compartment to be satisfied that the habit of spitting is in no sense a physiological necessity. This matter, as also that of placing a handkerchief before the mouth during coughing or sneezing, is one of popular education and in this connexion we must look to the National Association for the Prevention of Consumption to continue its admirable efforts. But I cannot help thinking that it is both undesirable and unnecessary to accentuate *too much* the phthisical aspect of the question and I am glad to see that this is apparently the view taken by the Home Office in approving by-laws directed towards the control of the spitting habit.

It seems to me that the most useful attitude which can be taken up is that the practices of unregulated expectoration, coughing, and sneezing are unwholesome practices calculated to spread disease and that therefore efforts should be made to control them. Let us avoid hysteria. Already much has b[illegible]n done, and in the matter of official by-laws the example [illegible] been set by the Glamorganshire county council, on the [illegible]itiative of its able medical officer of health, Dr. William [illegible]illiams, who has recently had the honour of being [illegible]ppointed by the Royal College of Physicians of London as the Milroy lecturer for 1904. This example of Glamorganshire has, I believe, already been followed by Radnorshire and a similar by-law is likely to be shortly in force in Worcestershire. The subject is also being seriously considered by other county councils. I was told recently by Dr. G. Reid (county medical officer of health of Staffordshire), by Dr. J. R. Kaye (county medical officer of health of the West Riding of Yorkshire), and by Dr. J. Wheatley (county medical officer of health of Salop) that the councils of each of these counties were contemplating action in this direction. The action quite recently taken by the London County Council will be cordially welcomed by all Londoners.

It appears to me that this is a subject of elementary cleanliness which might be promoted by every sanitary authority in the kingdom, not only as regards its value as to the control of tuberculosis, but in the interests of that general cleanliness which is likely to conduce to the prevention of several preventable diseases. The action which has been taken by numerous large towns with regard to the prohibition of spitting in tramcars and the exhibition of notices to the same effect in the carriages of the underground railways of the metropolis cannot fail to be appreciated by the public at large. The use of expectorating flasks or the employment of other means of rendering sputum innocuous by those suffering from pulmonary tuberculosis accompanied by expectoration is an obvious necessity, and the use and cleansing of flasks, &c., constitute one of the many advantages which accrue from a short stay in a sanatorium; indeed, this educational value of sanatoriums is not the least valuable of the uses to which these institutions may be put.

The disinfection and cleansing of infected dwellings.—Into the details of this matter I have no time to enter and I merely wish to insist upon the great importance in relation to the efficacy of both these measures of providing in new houses, and wherever practicable in old, impermeable and washable surfaces to the walls, floors, and ceilings in order that both disinfection and cleansing may be carried out at frequent intervals with the least possible expense and inconvenience. This is a provision which, like the control of expectoration, has [illegible] communicable diseases [illegible] ness and one which [illegible] all sanitary authorities.

Sanatoriums.—When dealing in my last lecture with the German statistics I discussed the influence which sanatoriums might be thought of as exerting in the limitation of consumption, and I need not refer at any length to the subject at the present moment. As curative agents these institutions are almost indispensable and in the matter of prevention they are likely to curtail the prevalence of the disease by aiding education and by reducing the number of advanced cases. No one who has studied the working of sanatoriums can doubt that they are of great value in a curative sense, but if only say 20 per cent. of those who leave the sanatoriums do so with their sputum free from bacilli there is still a very material margin, even supposing these 20 per cent. remained thus free until death, an expectation which is, I fear, not always realised.

Similarly, if we take the case of homes for advanced consumptives, institutions in which Professor Koch seems to have such very great faith as preventive agents, we should remember that we are only isolating cases of consumption which have been potent for harm since the tubercle bacillus first appeared in their sputum, possibly many years ago. I cannot altogether agree with Professor Koch that the cases which from their inability to carry on the battle further retire to their homes to die form the most dangerous class *quâ* infection. My own view is that the danger is greatest in the phase preceding that final withdrawal, during which time the patient is able not only to move about in his own home, but also to work, to occupy railway carriages, omnibuses, public-houses, and churches. During all this time he is, according to Flugge's school, spraying bacilli into the air in close confined spaces. He is also doing this in his home. I think, therefore, we may take it that to isolate only advanced cases, desirable as it may be as a matter of cleanliness, comfort, and humanity, is not a step which we are justified in telling the people will "stamp out" the disease. I think that Dr. Niven of Manchester is facing the problem in the only practicable spirit, when by the untiring efforts of his well-trained medical staff he searches out the cases, encourages cleanliness, practises disinfection, and advises the patient as to the best means of reducing the chances of infection. It is in the inculcation of the general principles of health, which include more air, more light, more cleanliness, and generally better housing, that we are pursuing the surest and the best tried road towards success. By all means let us have sanatoriums and homes for the dying, but do not [illegible] at if they spend their [illegible] at once and materially [illegible]

To those whose belief *it is* that the disappearance of leprosy from this and other countries was the direct result of the segregation of lepers and who hold that had no such segregation taken place the human species would have become extinct I commend a re-examination of the facts. I would also ask them to ascertain, if they are able to do so, the precise effect of isolation hospitals alone upon the prevalence of certain of the acute exanthemata. I venture to suggest that they may possibly emerge *from* their researches in a far from dogmatic frame of mind and that they may be inclined to view with less disfavour a thesis that the prevalence of unrecognised cases is capable of explaining in some degree the non-fulfilment of the prophecies of those who once proclaimed that isolation hospitals would completely "stamp out" the diseases for which they were intended. *This view in no sense leads, as some* suppose, to the conclusion that isolation of the acute exanthemata is a useless measure. On the contrary, an isolation hospital is, in my opinion, an indispensable unit of every properly equipped sanitary area, and the real value of such an institution will be the more apparent in accordance with the promptitude with which the cases of infectious disease are recognised and the use which is made of such cases in tracing out unrecognised or anomalous cases. Possibly such cases not infrequently outnumber the *recognised cases.*

Even as an isolation hospital is but a small part of the sanitary organisation of a well-ordered district, so is a sanatorium but a very small part of the whole tuberculous problem. In the matter of prevention the isolation hospital is much more important than the sanatorium owing to the far higher infective power of the acute exanthemata, for which such institutions are mainly utilised.

As regards the value of sanatoriums for pulmonary tuberculosis, one of the most experienced medical officers of health in England, Dr. Spottiswoode Cameron of Leeds, writing to me with reference to the work of the Leeds Sanatorium, states: "I regard what we are doing in the clearing of insanitary areas and the supervision we are giving to the subject of overcrowding as likely to do a great deal more for the prevention of consumption than the mere isolation of a few early cases in a sanatorium." Dr. Cameron is not, I think, alone in his views on this matter.

Difficulties seem to be experienced, especially in America, in providing sites for the erection of sanatoriums. I see in the *British Medical Journal* of July 25th that a Bill has recently been approved by means of which it is impossible for any city or "for any fraternal order, charitable society, or philanthropic individual," to establish a hospital or even a camp for consumptives except under practically prohibitive conditions. The Bill is, it appears, regarded by the *Boston Medical and Surgical Journal* as, to a large extent, putting an end "to the work of public-spirited citizens in New York State in combating and restricting the ravages of tuberculosis." All this is the result of a "mistaken idea of the dangers" of such institutions and it is against this very misconception that I am endeavouring in these lectures to protest.

And now let me very shortly draw your attention to some of the work which is being carried on in this country with regard to the provision of sanatoriums.

The action taken by county councils.—The powers which county councils now possess of providing isolation hospitals and the extent to which they are making use of such powers suggest that these bodies are better fitted than any other local authorities to provide sanatoriums. Up to recently, however, there has been some question as to whether the statutes enabled county councils to make such provision, but it has now been held by the Local Government Board that county councils can, by applying the expression "infectious disease" to consumption, solely for the purposes of isolation either provide accommodation for cases of that disease themselves or enter into an agreement with a properly constituted body for so doing. The application of the term "infectious disease" in these circumstances does not render the patient subject to disabilities under the Public Health Act. Action in this sense has already been taken by the Westmorland county council and it is likely that other countycouncils may soon take similar action. I am told by Mr. F. Vacher of the Cheshire county council that the local authorities in Cheshire are being circularised upon the subject and that if the majority are in favour of the county council providing sanatoriums action will be taken. Mr. E. Sergeant of the Lancashire county council, Dr. Reid of the Staffordshire county council, and Dr. S Barwise of the Derbyshire county council also tell me that the matter is under the consideration of their councils and Dr. Kaye of the West Riding county council has for some time had a very thorough scheme prepared. Certain other county councils have shown their sympathy with the movement by either contributing or expressing their willingness to contribute towards existing or projected schemes promoted by private enterprise. The county councils of Westmorland, Worcestershire, and Cornwall may be quoted in this connexion. I may add here that the problem with regard to the provision of sanatoriums generally has been materially simplified by the expression of opinion on the part of the Local Government Board in reply to a question from the corporation of Sheffield that sanatoriums are to be regarded as hospitals within the meaning of Section 131 of the Public Health Act, 1875

The actions of boards of guardians.—Boards of guardians in several places are now making efforts to provide separate accommodation for the tuberculous sick under their care and for the open-air treatment of such patients where this is practicable, even in the metropolis, and in large towns such as Liverpool and Sheffield great advances have been made in this direction and good results obtained.[3] But so far as I am aware the only case in which a new permanent sanatorium separate from the workhouse has been actually erected through the instrumentality of the Poor-law is that provided by the guardians of the city of Liverpool, a scheme which in its initiation and completion is largely due to the efforts of Dr. Nathan Raw who was good enough to take me recently over this institution and to explain to me the details. The three boards of guardians have combined and have obtained a provisional order which was confirmed by Parliament. They have now erected a substantial and admirably arranged building, situated at Heswall on an elevated site overlooking the Dee and the Welsh Hills and the institution was opened not long since by the Right Hon. Walter Long, M.P., President of the Local Government Board. It is a two-storeyed building providing 24 beds, 12 in each wing, the administrative department occupying the centre of the building and extending out to the rear; the cost, inclusive of the site, has been about £500 per bed. The guardians of the Bradford Union are, I believe, now making somewhat similar provision for their tuberculous paupers upon a site at Eastby near Skipton. The cost per bed will, it is believed, work out at about £220.

The proportions of this subject may be gauged by the fact that on July 7th, 1900, there were 1562 recognised cases of pulmonary tuberculosis in the infirmaries, workhouses, metropolitan asylums, and district asylums, and that during the year 1899 there were 2895 deaths in these institutions from pulmonary tuberculosis alone.

The treatment of tuberculous paupers on a large scale has recently been the subject of discussion in the metropolis and it is somewhat difficult in considering questions such as this to free oneself from the atmosphere of pity and, standing afar off, to take an impartial view of the position. Obviously we should all wish to see those who through ill-health have failed in the struggle or who are temporarily disabled put back into the ranks of the workers if even for a short time, but it seems to me that from the economical standpoint it would be wise to begin as it were at the other end of the scale and by the adoption of some such system as obtains in Germany secure treatment for the worker at the first onset of his illness. Indeed, I believe that Dr. Arthur H. Downes, the chief medical inspector for Poor-law purposes at the Local Government Board, has already expressed unofficially a somewhat similar view. It is conceivable that were elaborate provision made for the tuberculous paupers of the metropolis London might find itself in the position of having to provide accommodation for many tuberculous sick in excess of what might be termed its normal contribution—i.e., advanced tuberculous cases might seek refuge in the metropolis in order to qualify themselves for participation in its sanatoriums. From a philanthropic standpoint they would be welcome; from an economical standpoint the matter might be serious. The philanthropists and the economists appointed by the ratepayers must settle the matter. It is a social rather than a medical problem, albeit it is difficult to separate the one from the other.

Address

ON

THE DEVELOPMENT OF INSANITY IN REGARD TO CIVILISATION.

Delivered at the Annual Meeting of the British Medical Association at Swansea, July, 1903,

By ROBERT JONES, M.D., B.S., M.R.C.P. Lond., F.R.C.S. Eng.,
RESIDENT PHYSICIAN AND SUPERINTENDENT TO THE LONDON COUNTY ASYLUM, CLAYBURY.

Gentlemen,—The object of this address is to demonstrate that with the progress of civilisation mental breakdown becomes more serious and more frequent and the varieties of insanity are more chronic and less curable than in the early days of a century ago, when life was simpler and men were more content. It is a universal law that the most highly integrated functions of vital organisms are the most apt to suffer derangement.

The human mind—the most highly evolved process in relation to matter—has from the earliest times been subject to some obscuration or disintegration, but the cure and care of the insane, now so much in the "ambient air," was hardly known as a subject of serious study 100 years ago. The last century has been the most marked of any of its predecessors in regard to the material, mental, and moral progress of mankind and a short review of this progress with some lessons to be learnt from it cannot but be a matter of much interest to practical persons. Over many of us the history, the traditions, and the personal narratives of the past cannot but exercise a potent spell. We can learn from our failures as well as from our successes and these failures may possibly convey to us some notes of warning and act towards us as beacons and signals of danger. As, however, "hope springs eternal in the human breast" and our faith and aspirations are ever forward and to the future, some hopeful prophecy might be expected as to the alleviation, if not the prevention, of mental derangement; but will the lesson of our retrospect justify this anticipation?

---

[3] The Treatment of Tuberculosis in Hospitals and Infirmaries, Brit. Med. Jour., Nov. 8th, 15th, and 22nd, 1902.

The sum-total of the physical, moral, social, and religious energy which has caused our progress during the past century has been unparalleled in the history of man, but action and reaction are always equal and contrary and we shall find that our advance has not been without sacrifices—losses here and retrogression there—and that civilisation itself has not been an unmixed blessing, for in the struggle which has marked our advancement the conflict between intelligence and ignorance has resulted not solely in pure reason and limpid wisdom, but the path of progress has been freely strewn with mental wreckage and physical degeneration.

In the whole range of medical science insanity is, perhaps, of all others the most painfully interesting subject. It is the debatable land of the imagination which presents many subordinate varieties [illegible] poet, the fable of t[illegible] romancer being wov[illegible] excursions of mania [illegible] ness of unlimited po[illegible] source of mental delig[illegible] bliss much more exalted than fall to the lot of sober reason, but insanity in the self-condemnation and misery of melancholia inflicts far severer pangs upon its victims than can be produced by the most extraordinary anxiety and the most acute bodily pains. What are the consequences of insanity? It means in the first place a deprivation of liberty, perhaps a life-long maintenance upon the public purse—already heavily overburdened—a maintenance including housing, clothing, and food which tends each year to rise in cost. In addition to this useless life, or living death, a stigma probably attaches to those who are related to, and are dependent upon, the sufferer, by which they are made to feel the curtailment of the necessaries of life, increasing the liability to a similar breakdown in themselves. Surely, if the possession of reason be the proud attribute of humanity may not such a disease of the reason as insanity be ranked as the greatest affliction and is one not forced to make the study of such a disease which touches society, involves the law and defies medicine, one of deliberate and anxious thought?

What is it that characterises insanity? It is not the presence alone of delusions or hallucinations. There are many persons in daily life who fulfil all their duties and obligations to society and themselves and yet suffer from hallucinations. Insanity, although a perversion of mental functions, is not exclusively an intellectual disorder, for persons gifted with high intelligence may fail to respond to ordinary motives and become so defective in their habits as to be socially unfit to mix in the world. Again, the distribution of mental faculties may be so uneven and mental endowment may be so unbalanced that their possessors are unfit to be at large. There are many persons who are properly incarcerated in asylums, in whom there are merely exaggerations of normal tendencies, fluctuations of the mental faculties which may be described only as excessive or beyond normal limits and which render these persons unstable, untrustworthy, and even dangerous, yet in whom there is hardly, if any, loss of mind. It is only too well known that there are imperceptible gradations as well as abrupt transitions between health—which is the easy, harmonious, and unconscious performance of the organic functions—and disease. Health of mind, like health of body, is a somewhat indefinite expression.

I shall exclude from the subject of this paper senile forms of insanity, the mental decay of involution which results in more or less normal loss of mind, as also the primary defects of idiocy and imbecility which are pathological variations not entirely dependent upon individual stress and which exist in all grades of society and all states of civilisation.

So far as any trustworthy information is to be had it appears that insanity increases as man departs from the savage and semi-civilised states and approaches the highest civilisation. In primitive states of society and among uncivilised races insanity is rare, the pure psychoses are unknown, the chief forms—apart from the low grades, idiocy and imbecility—being associated with the taking of drugs and correspond to the insanities of civilisation resulting from alcohol, ether, cocaine, morphia, &c., and which in the main are curable. Insanities which end in dementia are rare and dementia itself is uncommon, and it is only when we come to higher civilisation that the higher forms of insanity are seen. Diseases, like the physical causes which produce them, have their evolution, their cycles; and their day, and I shall proceed to demonstrate that the progress of mankind has caused a more or less complete change in the type of insanity such as now comes under treatment. As to the causes of insanity, the actual and proximate exciting causes will always be stress of some kind acting upon an organism predisposed to break down, the great predisposition being determined by heredity and by the social environment of the individual, for we know that social relations and obligations constitute the preponderant factor in any mental life. As to heredity we need say no more than that an inherited instability of organisation makes itself evident in the present day more than in any previous period at the physiological crises of life, a hereditary tendency being responsible for more than one-third of all occurring insanity. The tendency of recent years to look upon insanity more as the result of bodily than mental causes is no new view. Haslam, in the early part of last century, classified the causes of insanity and insisted that the disease was never purely mental—that, on the other hand, positive bodily conditions were the causes and that insanity was structural and active in its origin. Earlier writers, however, laid great stress upon a disturbance of the emotions as a cause of insanity, sudden violent affections or the habitual indulgence of any passion whatsoever being looked upon as definite exciting causes. Those whose professions required the exercise of the imagination and the indulgence of the passion, such as the *personnel* of the drama, were said to be peculiarly liable to insanity, but probably some physical factor, such as a dissolute and irregular life, was concerned in causation. Fright, anger, religious terror, grief, ungratified desire, and disappointed pride were specially referred to by those earlier writers as definite causes of insanity. It was pointed out by Pinel that 30 per cent. of all his cases were due to domestic bereavement, 26 per cent. to the events of the Revolution, and 22 per cent. to fanaticism and disappointment in love. It is also an interesting record by Charles Booth[1] that the anxieties and uncertainties of professional life are responsible for the largest proportion of insanity which this class of all others shows He also points out that loss of trade affecting bodily health is responsible for causing insanity, and that provided wages are regular, although low and there is no nervous strain, there is little tendency to insanity.

As to civilisation, this means progress and it implies a development from the simple to the more complex. When the conditions of life become more specialised the nervous system of man has to react to more stimuli; not only are these more numerous but they are more complicated. For each stage of civilised life a special standard is fixed; the more perfect and the higher the standard the more culture and knowledge are attained and better results obtain in consequence. Highly civilised man thus lives in a more complicated environment, which calls for the higher forms of self-control and more prolonged and varied efforts than are customarily aroused by the simple emotions and the elementary sensorial stimuli of a primitive life. In these efforts numbers of unfortunate ones will not succeed, they are incapable of elevation to this higher plane of civilisation owing to mental, physical, and moral deficiencies. Not having the qualities essential to success they are left behind, evolution proceeding at the expense of the less fit—those, in fact, whom civilisation itself in the struggle renders unfit for the standard it has itself fixed. It is thus seen that civilised society, in forcing the pace, practically manufactures its own unfit—viz., its own paupers, its own lunatics, and its own criminals. London alone in this respect is responsible for the production of over 70 insane persons per week and this number is destined unrelentingly to increase. The only neutralising agency is the fact that sterilisation follows in the wake of three or four generations of town-bred people—a natural law which insures that the unfit shall cease to cumber the earth. Not that civilised life, properly developed, tends in itself to cause insanity, but by implying a more complex mental structure with more delicate parts and nicer construction, this mental machine is more liable to faults of mechanism and varieties of derangement than is the case with the simpler and more vacant minds of primitive people. In cities where the population has to accommodate itself to the pressure of competition the tension of mind is more continuous. There is an increased inhibition from pent-up mental energies which in a primitive life find a ready exit through muscular actions. In cities also artificial desires multiply, unhealthy activities are created, and ambition further forces the overworked brain, which, sooner or later, results probably in its complete breakdown. The wants of modern civilised life are many and are rarely gratified, the eager hand reaches to grasp the prize which is plucked away by some other of the numerous competitors, and bitter disappointment is added to the nervous strain and mental overwork. It is doubtful, however, if mental labour alone is ever an actual cause of insanity, for habitual application of the mind, when not excessive, strengthens it and renders it less liable to disease. Dr. F. W. Mott has shown that the best and most exact nervous reaction takes place when the nerve circle is complete and in a state of healthy tonus or strain. There is no doubt that fatigue is unfavourable to good mental work and by experience we know that fatigue is caused by intense thought. Böerhaave said that unremitting mental attention to a single subject for a whole day once kept him for six weeks without sleep. Bodily fatigue we also know to be demonstrably injurious to thought, for Kraepelin has shown that muscular exhaustion weakens brain power in definite curves and ratios. It is not overwork, however, so much as worry and anxiety which cause insanity. Civilisation, as we all know, brings in its train different effects to different groups of people. To the idle rich it brings sensuous luxuries of all kinds which account for the insanity of those in easy circumstances who are prone to much self-indulgence, who pay over-much attention to personal longings and sensations, and who have too little occupation or whose occupation is irrational and unhealthy. To the poor—the stratum in society which is most prone to insanity—who are at the mercy of every economic fluctuation, it brings lack of proper nutrition, overcrowding with unsuitable hygienic and moral surroundings, and all the other evils and abominations caused by the massing of people in large cities, such as alcoholic and other indulgencies, poverty, and crime, the latter an evil worse than poverty and which bears a very intimate relation to insanity—the instinctive criminal and the morally insane being considered to be identical individuals, characterised by the same psychical and physical stigmata of degeneration. As to overcrowding an immense number of poor people live in small and badly ventilated apartments with filth and squalor in their mean streets and dwellings. Their food is often deficient in quality and quantity, which predisposes them to physical and mental disease. How can vegetables, fish, and milk be fresh and digestible by the time these reach the poor of London where even the cooking for this class is stated on good authority to be worse than in the country. Surely the plainest food with health under a hedgerow must be better than such semi-starvation with the glamour of the city. Overcrowding leads to many and various miseries and personal discomforts which are humiliating and demoralising to the grown up and are a source of moral contamination to their descendents in whom they cause mental and bodily degeneration. All the year round these dwellers of the city are at a disadvantage compared to the country folk. In winter they suffer from cold, want of food and clothing, and in summer they endure a debilitating atmosphere from the reeking odours of dirt, decomposing garbage, and noisome refuse. The disposal of refuse, the sterilisation of milk, the detection of adulterations, and the provision of pure water are great problems which big cities have ever before them. London, probably the healthiest of these, breeds her legions of anæmic, hydrocephalic, and unhealthy children from the want of pure air and radiant light. Crowds of people have their happiness stifled by their environment in our great cities, with the result that they seek to drown their misery and depression in the effects of alcohol. This sedative taken to lull and to veil the little worries, the small pains, and the general mental disturbance of whole classes is the cause of at least a fifth of all insanity occurring in males and more than half this proportion in women—the proportions are probably much higher—and call loudly for definite action and treatment. Such indulgence leads to other sensuous excesses which are all deleterious to nervous centres. There is no doubt that London and, *a fortiori*, other towns produce in the present day a tension of the nervous system as baneful as it is unnatural. One has only to look at the living maelstrom which pours into airless and sunless London offices, workshops, and factories every day from the suburbs to see the strained, eager, earnest, and inwardly preoccupied people who are compelled to sacrifice their health and overstrung nerves in the cause of "civilisation."

---

[1] Life and Labour of the People.

Let us briefly contrast the state of civilisation a century ago with what it is to-day and see for ourselves the reason why the stream of progress has been strewn with physical and mental wreckage. Beginning with education the great mass of the people was entirely without it. At Queen Victoria's accession 44 per cent. of the community were unable to read and to write or even to sign their names. Now this proportion is less than 6 per cent. Another great change within the past century has been the migration of the population from rural districts into towns, which has been caused in the main by our present system of education.

In the first year of the reign of Queen Victoria sufficient wheat was grown in the land to feed the people for 11 months in each year, now there is only enough grown to provide the population for two and a half months. Furthermore, the cultivation of the potato—a measure of industrial as well as of arable progress—is declining in this country, where it is only 38 acres per 10,000 persons, as against 161 in Germany and 98 in France. In the year 1800 more persons lived in the country than in the towns, in 1841 the urban total was one half of the whole population, and in 1891 the urban constituted 77 per cent. of the whole population. Such a system of education which drives each year 80,000 persons from the country into the towns and, as Mr. Rider Haggard states, leaves the land without labourers and ploughmen, and which yet causes millions a year to be paid away to the little culturists of the continent for fruit and eggs and over half a million for onions alone, which can so well be grown in this country, is evidently unsuited for rural districts. Not until each local authority can determine what should be taught in each district, as foreshadowed in the new Bill, can any improvement take place. The present system of education is too rigid and the hard-and-fast curriculum of cramming should give way to a minimum of bookwork and a maximum of outdoor instruction so as to train the eye to observe and the hand to work. Shelley's diatribes against the selfish oppression of the people by the landowners and others were doubtless fully justified, but it is a question whether the political franchise has not extended power into the hands of masses of people who are incompetent to grasp issues involving great risks. What is now the condition of the villages, the looms of which were once in active work and where the handicraftsman once throve in patient contentment, feeling joy and pleasure at the performance of work done as well as it could be done? These handicraftsmen have now left for the towns, where they work in small, hot, and ill-ventilated shops and are at the mercy of every trade fluctuation, the curse of drink following on the heels of their uncertain occupations.

Perhaps in no department of human activity has progress been more marked than in that of communication. In the early part of the last century it cost 1*s.* 4*d.* to send a letter 60 miles, and in 1837, when the penny post was established, four letters were sent by each person annually, whereas now 100 letters and two telegrams are sent and a staff of 160,000 is employed exclusively in this department. In 1830 the only railway was from Liverpool to Manchester and at the late Queen's accession in 1837 there were only 110 miles of railway which were opened in spite of prolonged and strenuous opposition. Although steam was used on the Hudson in 1807 it was not until the second year of the reign of Queen Victoria that it was used to cross the Atlantic. A century ago there were no telephones or telegrams, no steam, and no electricity. Means of communication were rude and costly and only the well-to-do could travel, roads were bad, and tolls and turnpikes were frequent. The stage coach was the only conveyance for the many, but life in the open air tended to chivalry and to courtesy. Our ancestors read less than we do, but their reading was of a more solid and enduring character than is ours.

The scarcity of books and the comparative rarity of journals induced readers to master what they read, with the result that they absorbed real nourishing intellectual food. A superficial attention to an ill-digested course of reading dulls and benumbs the intellect. I have had not one but several youths whose insanity was distinctly traceable to the injurious tone of the literature which they indulged in. It is also stated, by those best qualified to give an opinion, that this steeping of our youth in the prurient, exciting, and unreal literature of to-day—a literature that crowns even vice and crime with an illusory halo of glory—has been the principal cause of neglected domestic duties, unhappy homes, and a large percentage of crime, as is frequently testified in the summing-up of our magistrates.

The emancipation of women from unfair and unjust disabilities and the larger measure of education and freedom granted to women have especially marked the last century; but it is a serious assertion that they look with complacency upon the conjunction of an increased marriage-rate and a diminishing birth-rate. It is believed that the idle women of the upper classes (who are more self-indulgent than ever before) regard the immorality of the average man with less aversion and that they bewail the injustice of visiting condign social ostracism and punishment upon women for similar delinquencies. Further, the revolt against domestic service among the lower classes is also to a great measure a reflection of the love of pleasure in high places.

I do not deny that vast improvements have taken place in the social condition of the people in the past century. But what have been the physical and psychical effects of progress upon the nation? In spite of the progress in sanitation—the science of preventive medicine—which concerns the great tripod of life—food, air, and water—and which now forms one of the most important departments of medical education—a science which in the late reign has caused £150,000,000 to be spent in providing pure water alone, which has directed special attention to temperance, to the reduction of mortality (the rate of which has declined from 1 to 23 in 1685 to 1 to 40 in the middle of the century, and at the present day to 1 to 55), and especially to infant mortality, calculated by the proportion of deaths under one year of age to 1000 births, which, according to the Registrar-General's information, was yet higher in 1902 than 1881, and to the protection of adult and child life by special statutes, yet I say that in spite of all these facts the physique of the nation has deteriorated, the deaths from cancer and nervous diseases have absolutely increased, as may be seen from Table I.

TABLE I.—*Showing the Annual Death-rate per 1,000,000 Persons.*

	1861-65.	1886-90.
Cancer	367·8	599·7
Nervous diseases	1546·0	1785·3

Furthermore, out of 1000 consecutive male cases admitted into Claybury Asylum 143 were between the ages of 15 and 25 years inclusive, and these are typical of their class. Table II. gives the actual physique of these 143 persons in weight and height at the respective age period, compared with the averages in the general population at the same ages.

TABLE II.—*Giving the Physique of 143 Persons admitted into Claybury Asylum in Weight and Height at different Age Periods, compared with the Average General Population at the same Ages.*

Number of patients.	A [illegible]	[illegible]	Healthy [illegible] age.	Average weight of patients.	Healthy standard of weight according to age.
		Inches.	Inches.	Pounds.	Pounds.
1	15	56	61	64	103
6	16	61	63	109	117
4	17	64	65¼	117	130
12	18	65	65¼	120	142
16	19	64	65½	122	139
13	20	65	65¾	123	138
22	21	66	66	130	145
17	22	64	66¼	130	141
16	23	66	66¼	128	145
20	24	66	66¼	132	145
16	25	64	66¼	127	144

Does not the above point to a physical degeneration in certain strata among a large number of the population for which some cause should be found? I know it is asserted that the growth of the upper classes has increased, but where is the proof of this? Talbot and Kingsley have recently called special attention to the contracted jaws and the poor teeth of town-bred persons, and the attention recently called by the Royal Commissioners on Teaching in Scotland, by the report of the Inspector-General of Recruiting who states that one out of every three persons brought up by the recruiting sergeant is rejected, by the special report of the Director-General of the Army Medical Department, by Sir Lauder Brunton and many others, deserves most careful inquiry and investigation. It is stated that there are at the present day more feeble-minded among the children of the metropolis in proportion to the population than ever existed before, and it is computed that there is one such for every 180 healthy children who requires special educational care and training. Not only is there thus a lowering of physique among town-bred people, but their mental condition is also affected and some remedies should be pointed out towards the more efficient progress of our present system of civilisation.

The cult of athleticism which has become the absorbing passion of Englishmen, old and young, must be looked upon as, on the whole, a corrective of neurotic heredity, but it is not certain whether excessive exercise does not lead to overstrain of the circulatory system for which future generations may have to pay heavy penalties. Already cardiac diseases unknown in the early years of the last century are calling for special methods and institutions for their treatment and cure. The seriousness of high arterial tension is being discussed on all sides and tonics in the form of phosphorus, arsenic, and strychnia are much more common, as also are cardiac sedatives. In Germany much attention is paid to suitable open-air play places exclusively for children and teachers are appointed to play with them. There is no doubt that physical culture is one of the greatest needs for our young people of to-day. I can speak in high praise of Swedish drill as a successful addition to the treatment of the insane. Its use has been very beneficial in the experience of my colleagues and myself at Claybury. It is a system which connects mental and muscular processes, engages the attention, and insures a more precise and ready reaction to outward stimuli.

What have been the psychical effects of "civilisation"? As regards education the present system has doubtless raised the general intelligence of the community, but it has destroyed individuality, it does not train the eye to see, the hand to work, or the imagination to create. Few men of the first rank now rise from the masses. It is also said by those who know that respect for personal qualities has disappeared and has given place to respect for the longest purse. This adoration of the millionaire demonstrates the craving for luxury and the means to obtain pleasure and it permeates every rank of society. Men now think they have a right to gratify every passion irrespectively of the misery this may involve to those dependent upon them. The question is whether the pendulum has not swung dangerously far in the direction of toleration and whether liberty has not degenerated into licence. Already there are not wanting signs that legislation is being called for to deal with prodigals, spendthrifts, and persons guilty of gross self-indulgence. There is no doubt that to day altruism has lessened and individual selfishness has greatly increased. Our hospitals languish for lack of funds, charity has never been doled with less liberality, and our great universities—the pride of our country in the Middle Ages—make futile appeals for support. Benevolence, as in past centuries, does not in our day found great institutions for charity, education, and religious devotion. Further, the judicial statistics (1903) show that certain kinds of law-breaking are on the increase, there are more divorces than ever among the upper classes, and the petitions for dissolution of marriages in 1901—the last year reported upon—were higher than in any previous year. Orders made by the Summary Court for judicial separation have increased by 31 per cent. It is only too apparent that there is less general heed paid to marital constancy and the laxity of morals among the "smart set" of women cannot but exercise a baneful influence upon the future morals of this country. Commercial morality has declined, for crimes of embezzlement and betrayal of trust on the part of trustees, managers, secretaries, clerks, and the like, have shown a decided tendency to increase. There is a dearth of sincerity and of men who "run dead straight."

As to the sharp differentiation and subdivisions of workmen into groups, pointed out by Charles Booth, is it now certain that these groups do not hurry to get through their tasks so as to "enjoy themselves" in some banal and senseless amusement and that their work is performed indifferently and without pleasure in contrast to the individual attention from the workmen of former days, who, as stated, showed their joy in work well done? It must not be asserted that when wages are high the people are contented. The reverse is often the case and it would be true to say that there has never been an age more discontented than the present. Socialism, that feeling of the body politic in the aggregate which levels down rather than up and which provides for the many at the expense of the few, tends to the extinction of individual enterprise of every kind. It tolerates, if it does not sanction and encourage, the present state of nearly one-fourth of the wage-earning population who are reported to exist at rates of wages just above starvation and who never rise with, or participate in, the country's prosperity. This socialism is favoured, if not determined, by the fact that the preponderating vote of the elective body decides the policy of the elected body. Under this system, among other developments, a vast amount of municipal indebtedness has been incurred and so serious is this that the president of the Incorporated Association of Municipal and County Engineers (Mr. Weaver) recently called attention to the increase of 216 per cent. in local indebtedness which has taken place during the last quarter of a century and which, to prevent municipal bankruptcy, can only result in the nationalisation of municipal loans. The spirit of chivalry and courtesy already referred to has certainly all but disappeared. The difficulties of travelling in past days made women much more dependent upon men than they are to-day, for travellers in their hurry and scurry to "catch the tube" have no time for courtesies and no occasion for gallantry. On the other hand, women being more free are more addicted to pleasure than they ever were before and they find this in the excitement of gambling, for they have become more the companions of men in sports and pastimes. It is also certain that the women of to-day drink more alcohol than formerly and to a great extent secretly. As to the general question of alcohol, the subject will be dealt with fully in the debates of the section and I shall not further allude to it here.

From what has already been said—and we are much indebted to Mr. James Stanley Little for his records[2]—it is seen that high pressure and a subdivision of labour have evolved a very complicated mental mechanism with every possible liability, therefore, of getting out of order, which has resulted in the appearance of a large variety of mental diseases unknown to the older physicians. We shall see the import of this in our comparison of the diseases of to-day with those of 100 years ago.

It is interesting to note that the first serious legal enactments in our country respecting the care of the insane do not date back farther than the second or third year of the reign of William IV. By the courtesy of the Commissioners in Lunacy I am informed that some statistics date as far back as the reign of Edward II. Possibly the mental infirmity of King George III. gave an impetus to the more enlightened modern treatment of mental diseases which, until about this period, was not only a reproach but also highly reprehensible. Before this reign we have no noteworthy records of asylums other than Bethlem. St. Luke's Hospital had been opened less than ten years, but from 1762 to 1822 we have valuable contributions in regard to mental diseases from Cox of Fishponds,[3] Arnold of Leicester,[4] and Haslam of Bethlem Hospital[5]—an institution in which the skilful and kindly treatment of mental diseases was then, as now, an honour to our land. About the year 1793 we have the work of that great champion of the rights of the insane—viz., Pinel of the Bicêtre translated into English by Davis[6] of Sheffield, a philosopher, a scholar, and a physician. Haslam was the first to describe general paralysis of the insane, a disease which is probably the most highly evolved form of mental breakdown, and at the opposite pole to the primary defects of idiocy and imbecility. General paralysis was then rare, but is now so common that Dr. T. S. Clouston, in his last report of Morningside Asylum, considers it to be in the proportion of 21·7 per cent. for male admissions and 6·7 for female admissions as against 17·3 males and 3·3 females for the whole of the London County asylums. Whether the disuse of mercury as a general therapeutic remedy in our day compared to the frequent salivation for the smallest ailments in the past may have anything to do with this increased prevalence is uncertain and too speculative to be considered here.

There is reason to think that syphilis is more common now than it was a century ago (although the opinion of Sir Alfred Cooper dissents from this view) and it is possible that its dire effects upon the nervous system might be controlled, or modified if not altogether avoided, if these were more generally known or if information respecting the far-reaching effects of syphilis and the nature of the disease were more widely disseminated. The ravages in India among our troops have given rise to loud cries for special protective legislation against contagious diseases of a luetic character and only last year a unanimous resolution was conveyed from the section of Psychological Medicine of this association urging the attention of the Government and public bodies to the horrible results of this disease, but our statesmen are timid about the health of the people when fanatics, faddists, conscientious objectors, and other irresponsible agitators begin to make political capital out of the "moral" question. It is not too much to say that the more highly developed a race becomes the more cases of general paralysis and other forms of insanity due to the same cause will occur, and it is not too much to infer that the diseases named are preventible and should be prevented. Haslam refers, before the year 1800, to the disease described as dementia præcox, then so rare but now so common that it may almost be described as the scourge of our asylums, for it attacks prematurely our most promising youth, it is practically incurable, and helps to fill our asylums of the future with the hopelessly insane. It is of all forms the one caused by overstrain and the mental rather than the manual worker is subject to its ravages; also, as stated, the great majority never recover from it. This is Haslam's description of it in 1800: "A species of insanity sometimes occurring about the time of puberty, especially in those who have possessed a good capacity and a lively disposition and in females more frequently than males, their faculties are gradually obliterated until they are at last complete and incurable idiots." That which was then occasional may now be described as having become a common variety of insanity among our promising and educated youth.

Haslam reported prior to 1806 upon the treatment of 8874 cases of insanity (4042 males and 4832 females) in the second Bethlem Hospital, built in Moorfields in 1676, and the result of 46 years' experience. The maniacal form of insanity was then more common. Those were the days when men were content and the nation had faith in its destiny. In the *Times* of July 11th, 1803, was published a war song in which, after inviting the consul-king to attack us, it proceeds:—

> " . . . . that Britons
> Can fearless still maintain their stand,
> And single-handed crush the pride of France."

All classes then bore the necessary hardship of high taxation with resignation and without discontent.

As to the recovery-rate, Haslam states that his own among cases of mania was 67 per cent. Last year in all the asylums of London the recovery-rate from all cases of mania amounted to 38 4 per cent. There were few insane in those days but those which occurred were acute and curable. Not until Jan. 1st, 1859, was the number of lunatics officially registered in this country. At that date there were 36,762 insane persons, a proportion to the population of 1 to 536. To-day they number over 113,964, a proportion to the population of 1 to every 293, and the tendency of much of the insanity which comes under treatment to day is to end in dementia and to become incurable. Even a quarter of a century ago the type of insanity was different from that of to-day. There is an increased tendency to melancholia which is less recoverable than mania, being probably a deeper reduction of nerve elements than occurs in mania. Melancholia has shown a considerable rise among the educated and private class of the insane, and I am stating a fact and not an opinion when I say that recovery may be complete after a sharp attack of mania, whereas this is rarely the case after melancholia, more especially in men. This supports the opinion of the earlier physicians that "furious insanity is much more curable than melancholy madness," both Haslam and Pinel having recorded this observation.

[6] Pinel's Treatise on Insanity, translated by Dr. Davis, 8vo, Sheffield, 1806.

Of all the 9267 patients (4096 males and 5171 females) who have been under treatment in the Claybury Asylum since its opening—a period of ten years—and of whom I have direct personal experience and record, 1132 males and 1625 females recovered, a percentage of 27 males and 31 females. Of the 8874 at Bethlem Hospital (4042 males and 4832 females) referred to above and under treatment over 100 years ago 1155 men and 1402 women recovered, a proportion of 27 per cent. for the men and 29 per cent. for the women, an improvement in the recovery rate of to-day of just over 1 per cent., in spite of all the means of treatment which a century's progress in applied art and the sciences has placed at our disposal. Surely there must be some other explanation than the failure of modern therapeutic means. May not this be discovered in the changed type already referred to and incident to our civilisation?

*If a comparison is made between the reports of the Com*missioners in Lunacy for the years 1878 and 1902—a period of 25 years—which, as stated, is within my experience, a reduction is seen in the percentages of all cases of acute insanity recorded, a decrease from 75·3 to 70·9 per cent., and further, as cases of *dementia præcox* or premature dementia in young persons—already referred to—were not recorded in the statistics of 1878 and they almost invariably commence in depression, it is justifiable to conclude that they were classed as melancholia, which has risen from 21·5 per cent. in 1878 to 27·9 per cent. in 1902, the reduction in cases of mania in these years being from 53·8 per cent. to 43 per cent. The age periods in the statistics of these Blue-book reports are not given but the calculations ascertained are absolutely confirmatory of the statements which I have made. As to the recovery rate the Blue-book for 1878 gives it for males as 34·81 per cent. and for females as 42·84 per cent., an average total of 38·84 per cent., whereas for the year 1902 the recovery rate is given as 34·4 per cent. for males and 39·7 per cent. for females, an average total of 37·1 per cent., an actual decrease in the recovery rate for the first and last of the 25 years under review.

With the progress of civilisation, therefore, not only is insanity on the increase but the occurring varieties are less curable; the physique of the town-dwelling section of the population has deteriorated both in height and weight, and the statistics of recovery are less favourable to-day than they were 25 years ago. Serious as this may appear, while such a state exists one can neither hope for nor expect relief from the great financial and economic burden of providing accommodation for the insane in the future. If relief is to come it will be in some great change affecting the physical as well as the mental health of the masses of the people—a foreshadowing of which is beyond the scope of this paper.

There is yet one factor in the psychical condition of the people which affords opportunities for high ideals, which kindles a spirit of sympathy, devotion, and fervour even among the roughest characters and in the most crowded areas of our cities—I refer to the effect of spiritual influence. In an assembly such as ours I touch upon it with extreme diffidence, but it is an element in human character for which even the Prime Minister has recently appealed, and the life of Father Dolling, the work of such institutions as the Salvation and the Church Armies testify to its influence over the mental and moral character of those hopeless persons who become the deposit of our civilisation. The indifference of the great bulk of the people to this aspect of life is a matter of common knowledge and an interesting contrast has been recently furnished in the July number of the *Edinburgh Review*. At the present time there are in London alone over 700,000 young men between the ages of 16 and 21 years—and mostly sons of working men—who need special guidance and training. It is not improbable that "hooliganism" and other forms of social outbursts might be much modified through an influence from this direction. Everything points to the *strong and immediate necessity for preventing the extension* of this lowered mental and physical vigour. Our zeal, energy, and skill should be directed to assist a more healthy adjustment of the mind of man to his ever-varying and progressively complicated environment.

PERNICIOUS ANÆMIA FOLLOWING PARTURITION.

BY WILLIAM ELDER, M.D., F.R.C.P. EDIN.,
PHYSICIAN TO LEITH HOSPITAL,
AND
EDWIN MATTHEW, M.A., M.B., M.R.C.P. EDIN.,
ASSISTANT PHYSICIAN TO LEITH HOSPITAL.

DURING the early months of 1902 there were under observation in the wards of Leith Hospital a number of cases of anæmia following labour. In all but two the anæmia was simple in type and the condition was relieved by the administration of iron over a period of three or four weeks. Two of the cases, however, terminated fatally and *from the general symptoms, the condition of the blood*, and the result of a post-mortem examination of one of them the conclusion was arrived at that in these two we had to *deal with an anæmia of the progressive pernicious type*. Both cases occurred in comparatively young women, aged respectively 29 and 31 years, and in both the condition either immediately followed labour or was very much aggravated by it so that a fatal termination occurred within a short time.

CASE 1.—The patient, a married woman, aged 29 years, was admitted to Leith Hospital in March, 1902, under the care of Dr. Elder. She complained of general weakness and had been ill for four weeks. Her family history was good. She lived in a comfortable home and had been married four years and had had three children. The labours were easy and in none of them had there been post-partum hæmorrhage. During her last pregnancy she had not felt in her usual health but was able to be about and to do her housework. For 14 days before labour she had been troubled with vomiting. The labour, which took place four weeks before admission, was normal. The sickness stopped after it and for ten days she felt quite well. On the eleventh day she had one or two shivering fits. These recurred daily for about ten days. The right breast suppurated, discharged for a few days, and then healed up. Ten days after labour she herself noticed that she was becoming yellowish in the skin and pale. *General weakness set in and the pallor increased.* She came for advice to the out-patient department and was admitted to the ward on March 15th.

On admission the patient was very weak and unable to stand on her feet for more than a few minutes at a time. She was very pale and not well nourished, but said she had always been thin and wiry. The lips were almost colourless. The teeth were very bad and the tongue was pale and dry. The appetite was poor but previously to the present illness the patient said that she had had no stomach troubles. She had been habitually constipated. On examination of the abdomen there was no tenderness. The stomach was not enlarged and the liver dulness was normal. The apex beat was faint and the pulsation was diffuse. The usual hæmic murmur was present at the base with a *bruit de diable* in the neck. The pulse was 120, regular, and of low tension. The urine was highly coloured and scanty. There were no abnormal constituents. The respiratory and nervous systems were healthy and the reproductive system was as stated above.

A drop of blood was obtained with difficulty from the ear and the thumb. It was very serous and on cover-glass films it looked almost colourless. The analysis of the blood gave *the following result: hæmoglobin, 20 per cent.; red blood corpuscles, 1,100,000 per cubic millimetre; and white blood* corpuscles, 6000 per cubic millimetre. Film preparations stained with the triacid mixture had the following characteristics. The red cells showed great differences in size and over 30 per cent. of them were megalocytes. Most of the megalocytes had increased hæmoglobin content and were opaque. Poikilocytosis was present chiefly in the form of oval and pear-shaped cells but was not so marked as the degree of anæmia would have led one to expect. Nucleated red cells were fairly numerous, the majority being megaloblasts. *Over 60 were counted in three very thin films.* Three or four of the megaloblasts in each field were giant cells. Mitotic division was seen in one nucleus. In most of the megaloblasts the protoplasm stained a dark brown with the triacid mixture. A few myelocytes of large size were seen in each field. The last examination before death showed an increased number of megaloblasts and a marked ante-mortem leucocytosis.

The patient lived for only seven days after admission to the hospital. She gradually became paler and very weak. The temperature rose on the second day after admission and remained at about 102° F. till death. For two or three days before death the patient complained of pain in the abdomen and had some sickness and diarrhœa. No post-mortem examination was made.

CASE 2.—The patient, a married woman, aged 31 years, was admitted to Leith Hospital on Feb. 11th, 1902. She complained of general weakness of nine weeks' duration. Her family history was good and she had a comfortable home. She had enjoyed good health up to three years previously. Almost immediately after marriage she had an attack of influenza from which she made a slow recovery. Two years and three months before admission her first child was born. Labour was prolonged, lasting for four days. The forceps was used, the perineum was torn, and there was considerable post-partum hæmorrhage. She was very ill for 14 days and then improved slowly, but was an invalid for quite three months. She nursed her child all the time and continued to do so for 13 months. Her second child was born nine weeks before admission. She was quite well all through the pregnancy. Her labour was instrumental and there was no post-partum hæmorrhage. She was in bed for ten days but though she got up after this she was never again able to work. During the first week of the puerperium she suffered from ulceration of the tongue and throat. About 14 days after the birth of the child she noticed that she was becoming very pale. About this time also she was troubled with vomiting and diarrhœa which under treatment were relieved. As the weakness was increasing she came into Leith Hospital.

On admission her lips were very pale and her teeth were very bad, especially the upper set, consisting as they did of a row of decayed roots, not one sound tooth being present. The appetite was good. She had no history of stomach troubles. Constipation had been habitual. She had suffered from palpitation and breathlessness since the child was born. The apex beat was weak and pulsation was diffused. A hæmic murmur was present at the base. The pulse was 112 per minute, irregular in time and force, and of low tension. There were signs of consolidation at the right apex. The urinary and reproductive systems were healthy. There were no enlarged glands and the spleen was not enlarged. The blood was very thin and pale and a count gave the following result: hæmoglobin, 20 per cent.; red blood corpuscles, 550,000 per cubic millimetre; and white blood corpuscles, 5000 per cubic millimetre. Films were stained with Ehrlich's triacid mixture. Marked differences in size were observed and a large number of megalocytes were present, the majority of them being stained polychromatophilically. Most of the cells were misshapen, oval cells predominating. Erythroblasts were present in considerable numbers; nearly all were megaloblasts, which in a count of five films averaged 150 per cubic millimetre. A few myelocytes were found in each film. A blood count on Feb. 21st resulted as follows: hæmoglobin, 10 per cent.; red blood corpuscles, 400,000 per cubic millimetre; and white blood corpuscles, 3000 per cubic millimetre. For a few days after admission the patient said that she felt a little better. She, however, got gradually weaker and died on Feb. 22nd, 11 days after admission. For 24 hours before death she complained of severe abdominal pain.

Necropsy.—At the post-mortem examination there was general pallor of all the organs. A few tuberculous nodules were present in the apex of the right lung. The heart was very pale; it contained a considerable quantity of fluid blood and beneath the pericardium were many small irregular hæmorrhages. The spleen was purplish in colour, of firm consistence, and showed thickened trabeculæ. Microscopic examination showed few or no iron granules. The medulla of the suprarenals was very small. The alimentary canal showed no naked-eye lesions. The bone marrow of the humerus and femur was examined and found to be red throughout. Smears were examined microscopically from the bone marrow, the liver, and the spleen. The bone marrow showed megaloblastic degeneration. Normal red cells were present, as were also numerous erythroblasts, almost all of which were megaloblasts and gigantoblasts. The white cells were mostly large, mononuclear, and non-granular. The liver was very pale and fatty and also had a mottled appearance. Sections under the microscope showed a large quantity of pigment in the liver cells consisting of yellow granules uniformly distributed and deposited in the outer two-thirds of the lobules. Ferrocyanide of potassium and diluted hydrochloric acid showed the pigment to be free iron. The spleen showed no excess of iron. There was no deposit of iron in the tubules of the kidney which, however, showed desquamative nephritis. (May this absence of iron from the kidneys not be explained by the nephritis impairing the excretory action of the kidney cells?)

Remarks.—That anæmia following parturition occurs with considerable frequency is well recognised. There is usually at the same time some causal factor—either small but repeated losses of blood during pregnancy or a more or less severe post-partum hæmorrhage—which amply accounts for the condition. The result, too, is favourable and most cases are relieved in a few weeks' time. In none of these, however serious the loss of blood may be, does one ever get a picture which is anything more than that of a severe secondary anæmia. It is extremely difficult in face of the most recent investigations into the causation of anæmia of the progressive pernicious type, attempting as they do to include that disease among chronic infective troubles, to assign to pregnancy and parturition their share, if any, in the production or even aggravation of such a condition. Earlier observers in their etiological classification of anæmias of the progressive pernicious type almost always included pregnancy and parturition as factors in a considerable number of their cases. Eichhorst in his etiological grouping includes under secondary pernicious anæmia 29 cases in which pregnancy and child-birth were the causal factors. Osler in his 27 cases includes five which followed parturition and in which an anæmia developed not to be distinguished from idiopathic pernicious anæmia. Of late years, however, not only have reported cases of pernicious anæmia following pregnancy and parturition been very infrequent, but by writers they have been excluded as etiologically having no influence in the origin of the disease.[1]

Ewing in his book on the "Clinical Pathology of the Blood" refers to the gradual disappearance from literature of cases of pernicious anæmia following pregnancy, mentioning that Ehrlich could find only one case in recent literature—one under the care of Laache recorded in 1883. Ewing himself a Sloane Maternity Hospital from 1892 to 1899 saw many case of severe anæmia but none of the progressive pernicious typ He concludes that the "rather numerous current reports o severe anæmia following pregnancy refer to a secondary typ of anæmia." Pregnancy therefore has no specific influenc in the origin of the disease and the veritable cases whic follow parturition are probably "referable to hæmorrhag and various unhygienic conditions."

It is very doubtful indeed if even the most severe secondary anæmia ever passes over to the pernicious type. In the two cases above recorded a typical anæmia of the progressive pernicious type was present in each, as evidenced by the reports of the blood examinations and the post-mortem examination held on one of them, and, further, we could absolutely exclude such conditions as hæmorrhage or unhygienic surroundings as in any way having been causal factors in the production of the anæmia. In both cases we found, as far as could be ascertained, two healthy women up to the date of their last pregnancies. During the course of the pregnancy there was only a history in one of them of some slight ill health, as compared with her previous condition. She was always able to be about and to do ordinary household duties. In both also we found after labour, without post-partum hæmorrhage, a sudden onset of a rapidly progressive anæmia, terminating fatally in one case in five weeks and in the other in ten and a half weeks. It is, of course, impossible exactly to fix the date of onset of the anæmia, but it is more than probable that in both the condition which underlies the production of such an anæmia did not begin to operate till after labour and this sudden onset, combined with the rapidly fatal termination, would seem to indicate some relationship between the anæmia and parturition in both cases. Dr. Hunter in his work on "Pernicious Anæmia" associates a chronic infective gastro-enteritis, following on decaying teeth, with the etiology of the disease. It is curious that in both these cases and more particularly in Case 2 we found a very bad condition of the teeth present, without being able to obtain any history of chronic gastric or intestinal troubles in either. That they may have existed, have been slight, and so difficult to elicit we have to admit. Both these cases would then be looked on as etiologically following Dr. Hunter's classification. In Case 2 in which a post-mortem examination was made, the stomach and intestines were reported to be healthy, but even if still we admit the gastro-intestinal tract as the site of the infection, such a causation fails to account satisfactorily for the very sudden onset or aggravation of the condition after parturition. From the group of idiopathic pernicious anæmias we now know have to be separated cases which, both in the condition of the blood and in the state of the organs post mortem, give a typical picture of pernicious anæmia and can be explained etiologically by the presence in the alimentary canal of bothriocephalus latus and ankylostoma duodenale. In these cases the hæmolytic changes in the blood are probably the result of a specific toxin. For some days before death both in a degree, but more especially the patient in Case 1, showed toxæmic symptoms, as evidenced by the considerable elevation of temperature with some vomiting and diarrhœa. In these two cases and in others following parturition may not the hæmolysis similarly result from toxic products thrown into the blood after parturition, or if the condition be already present during or before pregnancy may not an aggravation of the already existing pernicious anæmia be produced by substances which chemically favour hæmolysis?

---

A CASE OF SEPTICÆMIA.[1]

BY F. J. STRONG HEANEY, M.A., M.D. DUB., F.R.C.S. IREL.,

HONORARY SURGEON, VICTORIA HOSPITAL, BLACKPOOL.

THE following case deserves to be reported as well for the interesting group of symptoms presented as for its bearing on the question of the efficacy of antistreptococcic serum.

On May 5th, 1903, I was called to see a woman, aged 21 years, complaining of headache, pains in the joints and muscles, and an eruption on the legs. A fortnight previously she had sustained an injury to the right great toe which in the course of a week had led to a gathering beneath the nail and a swelling in the groin. With the appearance of the swelling, pains developed in the joints and muscles. On two occasions the patient had shivering fits, lasting on each occasion for a couple of minutes. The rash was noticed on the twelfth day from the injury. Though feeling very ill and wretched the patient continued at her household work until the day before my visit, when after vomiting twice she broke down and took to her bed.

On examination the patient was flushed and breathing heavily. The eyes were somewhat bloodshot and the lips were covered with sordes. The tongue was dry, furred, and tremulous. The inside of the cheeks, the fauces, and the pharynx were swollen and of a dusky red colour. The temperature was 104° F. and the pulse was 100. The heart sounds were normal and the respiratory sounds, except for an occasional râle, were healthy. There were no evidences of abdominal disease.

The nail of the great toe was raised from the matrix by a collection of fluid which on incision proved to be turbid serum with a single drop of pus towards the end. The swelling in the groin consisted of a mass of inflamed femoral glands, tender to the touch but without sign of suppuration. The most interesting point, however, at this stage of the case was the variety of skin lesions presented. On the face were groups of herpetic vesicles in five different situations—viz., on the forehead, on the upper and lower lips, and on both lower eyelids. On the trunk and limbs were numbers of pustules grouped most thickly around the folds of the groins, armpits, and knees, and on the legs from the knees downwards. In this last situation but confined to the front and sides of the limbs a number of raised patches were seen, very tender and of a purplish-red colour which faded gradually into the surrounding skin—in fact, presenting the typical appearance of erythema nodosum. At this stage the arms were free from these erythematous patches but subsequently one did make its appearance over the left ulna. Subsequently, too, a scarlatiniform rash appeared on the dorsum of each foot and on those parts of the legs which were not already occupied by the pustules and erythematous nodules. This scarlatiniform rash, having persisted a single day in its original form, became purulent by the development of a thin but almost continuous layer of pus beneath the cuticle.

Having regard to the focus of suppuration and the implication of the femoral glands the presumption in diagnosis was in favour of a septicæmic process, but in the presence of erythema nodosum and joint pains I thought it better to exclude simple acute rheumatism by administering a short course of salicylates and accordingly the patient was in the first instance placed on ten-grain doses of salicylate of soda every three hours. This had no effect on her general condition. On the next day the temperature had risen one degree and the pulse had increased to 128. A loud systolic murmur was now for the first time audible, heard best over the mitral area and traceable to the axilla. A specimen of blood reacted negatively to the Widal test but showed an increase in the number of white corpuscles. A culture was made and gave a growth of staphylococci and diplococci. The presence of two distinct organisms was, of course, suspicious of an artificial inoculation of the culture, but a second specimen taken with most elaborate precautions having come to grief diagnosis had to be based mainly on the symptoms.

For the first four days subsequent to coming under observation the patient became gradually worse. On the fourth day on auscultation the cardiac murmur might be heard to alter its character from time to time, being at one moment soft and blowing and at another quite loud and harsh and obviously non-functional in character. The respiratory sounds had now assumed a peculiar character; both inspiration and expiration were prolonged and noisy, simulating to some extent bronchial breathing. Towards the evening of that (the fourth) day the scarlatiniform rash already referred to appeared and also additional clusters of herpes on both upper eyelids. Though no streptococci had been found in the blood I determined to try the effect of antistreptococcic serum and at 9 P.M. 10 cubic centimetres were injected. In the course of the night the temperature fell two and a half degrees and the patient felt easier. On the next morning from 6 A.M., to 10 A.M. it again rose and at 1 P.M. another 10 cubic centimetres of the serum were injected. The temperature again fell, but only to rise again to its former height after about 12 hours. The injections were continued twice daily with like result till May 12th and then once daily till the 14th, when the temperature was normal and showed no disposition to rise. The other symptoms progressively diminished in severity and the various skin lesions cleared up. The cardiac murmur continued quite loud till May 21st, when it, too, began to grow faint and by the 28th it had completely disappeared and has not since returned.

There are many points of interest in the case. As regards the nature of the fluid evacuated from the seat of the primary lesion, I have mentioned above that it consisted of turbid serum (there had been no initial blood effusion) followed by a drop of pus. I have often noticed in inflammatory conditions of the extremities that when the contents of the abscess are thin and serous rather than creamy and purulent the local and constitutional symptoms tend to be more severe.

As to the skin lesions, the occurrence of erythema nodosum is unusual in such cases. Erythema multiforme, with sharply defined outlines, is a commoner phenomenon. Since treating this case, however, I have read a report of a case of septicæmia by Sir Dyce Duckworth in which he noted the occurrence of typical erythema nodosum. The distribution of the facial herpes was in my experience unique. I have frequently seen a greater number of vesicles and sometimes a wider area of the face involved, but never a distribution over so many different branches of the nerve. Seven in all were affected.

There can be little doubt that the abnormal heart sounds which developed while the patient was under observation were due to acute endocarditis and the manner in which this condition cleared up was a source of great satisfaction to all parties concerned. But the result is in keeping with what we know of such cases. As a general rule, if the patient survives at all he does so with a sound heart, thus contrasting favourably in one respect with rheumatic endocarditis and its high percentage of permanent heart lesions.

As regards treatment, the effect of each injection was so marked and so uniform that recovery may fairly be attributed to the serum. Of late the reputation of this preparation has been on the wane, many writers denying that it is ever effective. In my humble judgment it is effective and the present case, in which no streptococci were found, suggests the idea that its efficiency may not be limited to those cases where the infection is due to the particular strain of organism used in producing the serum.

Blackpool.

CICATRICIAL CONSTRICTION OF THE ABDOMINAL WALL AND OF THE LEFT THIGH ATTRIBUTED TO COMPRESSION BY THE UMBILICAL CORD.

BY C. O. HAWTHORNE, M.D. GLASG., M.R.C.P. LOND.,
PHYSICIAN TO THE CENTRAL LONDON OPHTHALMIC HOSPITAL; ASSISTANT PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL AND TO THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN.

THE unusual conditions existing in this case[1] are clearly displayed in the accompanying illustrations (see Figs. 1 and 2). As is shown in the figures there is a narrow cicatricial band forming a complete girdle of constriction in the abdominal wall. This occurs on the posterior aspect of the body at the level of the third lumbar spine; on each side it passes forwards and slightly downwards just above the iliac crest and the circle is concluded in front at a point one and a quarter inches below the umbilicus. The cicatrix appears to involve only the superficial part of the skin but it grips the abdominal wall to such an extent that it produces a groove which in the anterior part is depressed from a quarter to half an inch below the surface. Behind there is some appearance of a double groove but this cannot be traced in the lateral and anterior parts of the circle. The lower part of the left thigh also shows a depression or furrow placed obliquely immediately above the knee. The skin here betrays no distinctly cicatricial change and the constriction is much less acute than that in the abdominal wall. These conditions have without doubt been present from birth. Unfortunately it has not been possible to trace the practitioner who was in attendance when the child was born—she is now ten years of age—and therefore expert testimony in reference to the then existing facts is not available. But according to the mother's statement, delivery took place at the seventh month and the grooves on the abdominal wall and thigh were occupied by the umbilical cord. The same witness credits the medical man with the remark that "had the pregnancy gone to full time the child would have been cut into three parts."

The chief feature of interest in the case is the question of the agency by which the grooves in the abdominal wall and thigh were produced. It may be assumed that at the time of birth these depressions were certainly occupied by the umbilical cord, because, apart from the mother's statement as quoted above, other cases have been recorded in which a loop of the cord has been found in somewhat similar constrictions, at least in the case of the limbs. Thus it may be fairly argued that there is a *primâ-facie* case in favour of the umbilical cord as the constricting agent. But the evidence is not quite conclusive, for it must be allowed that given, during intra-uterine life, the formation of grooves upon the surface from any cause whatsoever, the mechanical conditions are such as would lead more or less readily to the reception and retention of the umbilical cord within such depressions. It is therefore possible that occupancy by the cord may be not the cause but the consequence of these constrictions. Hence it must be considered whether there is any other feasible constricting agent. First of all in this respect comes the possibility of bands of tissue taking origin in connexion with the formation of the amnion. These are usually regarded as agents which may lead to intra-uterine amputation of the digits or limbs and some instances have been recorded in which they have been found actually constricting these parts. All that can be said in the present case is that there is no evidence of the existence or action of such bands. In the second place there is the suggestion that constrictions and amputations of the limbs occurring during intra uterine life are due, not to some external agent, but to a trophic or sclerodermic lesion which, whilst primarily affecting the skin, cuts its way, as it were, more or less deeply, and, in the most extreme instances, causes strangulation or even separation of the distal part. Dr. J. W. Ballantyne, who discusses this question in his latest work on "Antenatal Pathology," considers that "no satisfactory explanation of the production of the so-called spontaneous amputations has yet been advanced." In view of so authoritative a statement some reserve in the expression of an opinion is necessary, but it may be permitted to suggest that in the present instance there are facts which support the view that here at all events the umbilical cord is responsible for the existing conditions. Such facts are found more particularly in connexion with the groove on the left thigh. This, it will be observed, has not a circular but a spiral direction and form. Now whilst it may be conceivable that a trophic or sclerodermic lesion may produce a circular constriction of a digit or limb, it is less easy to imagine an oblique or spiral groove, such as is here represented, to be the result of such a lesion. Further, the skin forming the floor of this groove, though perhaps

FIG. 1.

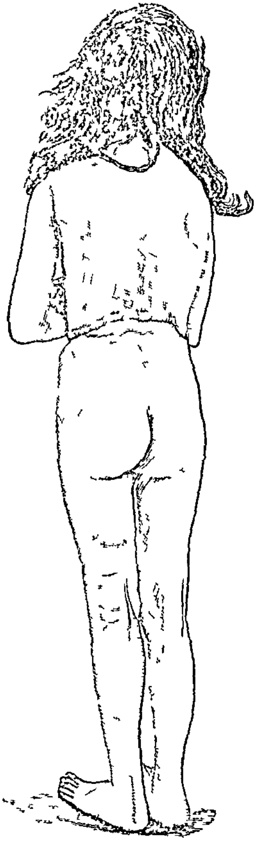
[1] The patient was shown before the Society for the Study of Diseases in Children in November, 1902.

somewhat atrophic, is apparently normal in every other respect; the appearances are just what might be expected from prolonged compression by a broad, smooth ligature Add to these facts the further fact (as it may be assumed to be) that the cord was found in the groove at the time of the child's birth, and the evidence supporting the theory that the cord is responsible for the existence of the groove is, it must be admitted, very strong, if not actually conclusive. But if this view holds good in reference to the thigh it must apply with almost equal force to the constriction of the abdominal wall It is only necessary to suppose a greater degree of tension to explain both the more marked depression and the definite cicatricial change This hypothesis also accommodates itself to the appearance of a double groove on the posterior wall of the abdomen with the existence of a single furrow in the rest of the circle, for in the former position the firm structure of the wall opposes a deep depression and thus a limited play of the cord from one level to another becomes possible, whereas the yielding nature of the lateral and anterior abdominal walls favours the ready formation of a deep and narrow furrow along the line of which the compressing action of a tense cord would be continuous

FIG 2.



Back view

Such a conclusion bears upon the question of the causation of intra uterine amputations. That the agency producing these is identical with that producing constrictions of the limbs is fairly certain, for in addition to the common sense presumption that amputation is merely constriction carried to an extreme degree, there is the observation that both conditions may be present in one and the same child An example of this association was recently shown at the Polyclinic, the case being that of an infant born minus several fingers and with a deep constricting groove around one leg But if intra uterine amputations are, or may be, due to the same cause as that which produces constrictions of the limbs, and if, as is rendered in the highest degree probable from the present case, such constrictions may be caused by the umbilical cord acting as a constricting agent, it follows that intra uterine amputations may also be accomplished by the cord or other band external to the body of the fœtus Hence the present case may be advanced as a contribution to the discussion of the mechanism of intra uterine amputations and its influence goes to prove that such amputations are caused by extra fœtal bands constricting in an extreme fashion the affected part. The argument in brief, therefore, is that intra uterine amputations and constrictions of the limbs are produced by one and the same agency, that, as is here shown, such constrictions may be caused by an external constricting band, in this instance the umbilical cord, and that consequently such bands must be held responsible for the occurrence of intra uterine amputations

Weymouth street W

OBSERVATIONS ON MASTICATION.

By HARRY CAMPBELL, M D, F R C P LOND,

PHYSICIAN TO THE NORTH WEST LONDON HOSPITAL.

IV[1]

MEANS OF INSURING ADEQUATE MASTICATION

IN order to secure the full advantages accruing from the use of the jaws and their appendages it is above all necessary for them to be adequately exercised during the period of development. If this is done not only will the tendency to dental caries, adenoids, indigestion, and other evils be greatly diminished, but the masticatory instinct will establish itself as a permanent force, so that the individual will tend for the rest of his life to subject even soft foods to thorough mastication The tongue, the lips, and the jaws of the newly born child find their natural exercise at the mother's breast and we should, therefore, do our utmost to get the mother to suckle her child, the bottle affording neither the same kind nor the same amount of exercise If, unhappily, we fail in this we must see that the teat of the feeding bottle is so constructed as to compel the child to earn his meal by, at any rate, some exercise This kind of exercise promotes the growth of the tongue and thus of the jaws, especially of the mandible Directly the infant shows a disposition to bite hard things the instinct should be gratified We may observe a tendency in this direction as early as the third or fourth month and it becomes more and more pronounced when, the time for the eruption of the teeth approaching, the gums begin to swell up and to get tender and saliva begins to flow from the mouth, it is now more than ever necessary to provide the child with hard substances on which to exercise the jaws and the gums, and a great deal of the trouble of teething is due to the failure to recognise this fact. What, then, are we to employ for this purpose? I am convinced that it is a mistake to rely solely, or even mainly, upon baubles of ivory, coral, and the like, useful though these may be in their way, it is far better to give the child something which is not only hard but nutrient and pleasant to the taste, something which will at one and the same time exercise the maxillary apparatus, excite the gustatory organs, and provide a certain amount of nutriment. To this end we may as the teething time approaches give a chop or chicken bone from which most of the meat has been removed, by powdering the bone with white sugar or salt we may increase its attractiveness From such bones a good deal of nutriment can be extracted, and this of a kind which is most acceptable to the infant stomach, for it must be remembered that the young human is in the main carnivorous. Indeed, since milk is a purely animal diet all the mammals must be regarded as essentially carnivorous during the period of suckling, while man, as already observed, from the time he emerged from the anthropoid until he learned to cook his food, was throughout life mainly an animal feeder. Therefore we should not hesitate to allow the teething infant animal food in the form suggested. Chicken and chop bones, yielding as they do before the pressure on the gums, are, moreover, just of the right degree of consistence for the purpose in view, while they afford abundant exercise for the tongue; ivory, coral, and the like are, on the other hand, too hard and unyielding and lack, moreover, the attractiveness belonging to sapidity.

---

[1] Nos I, II and III were published in THE LANCET of July 11th (p 84), 18th (p. 150), and 25th (p 2[illegible]6), 1903, respectively

By thus providing the maxillary apparatus with suitable exercise we shall do much to facilitate the eruption of the teeth and to favour the growth of the jaws and their appendages, including the salivary glands, and so to prepare the mouth for the reception of vegetable food. This should, of course, not be given till the teeth appear. The order in which these make their appearance gives some indication as to the order in which vegetable food should be administered to the child. The first teeth to penetrate the gums are the lower incisors which appear from the seventh to the eighth month; then follow the upper incisors from the seventh to the tenth month. These teeth enable the child to *bite*, but not, be it observed, to *masticate*, for which function the molars are necessary. Now the first molars do not appear till the twelfth or fourteenth month, the second molars not till between the fourteenth and the twentieth month, and it seems to me certain that our primitive ancestors could not have obtained starch in any quantity until they reached this age; at the best, pre-cooking man was but scantily supplied with starch, and such slender supply as he had could only be rendered accessible to the digestive juices by vigorous mastication which broke up the indigestible cellulose framework in which all vegetable starch is contained; hence until the young human cut his molars he had little opportunity of securing any starch. These considerations strongly suggest the desirability of giving but small quantities of starch before the twelfth month, and though the facts that ptyaline appears in the saliva about the time the first incisors are cut and that pancreatic juice develops its amylolytic ferment at the same time show that the digestive organs are ready for the reception of some starch at the seventh or eighth month, yet I believe the quantity should be strictly limited. I am ready to admit that the modern child may have, indeed probably has, a greater power of digesting starch than his remote pre-agricultural ancestor, but even so I am convinced that we should be on our guard not to over-gorge infants with this substance. Only a small quantity should be given before the twelfth month and it should be gradually increased up to the twentieth month.

I have said that the pre-agricultural infant was unable to secure starch in any quantity by means of his incisors. These teeth enabled him, however, to obtain some soluble nutriment from fruits and Dr. Sim Wallace has suggested that the early eruption of the lower incisors is for the purpose of enabling the infant to pierce the outer covering of fruits so as to permit him to extract the soluble contents by suction; and accordingly when these teeth are cut we may allow the child to bite at such vegetable substances as apples, oranges, and sugar cane. The latter is a useful article of diet for children, for it provides soluble saccharide in a diluted form and it is advisable that the child should receive his cane sugar well diluted, for it must be remembered that before the agricultural period man's supply of pure sugar was limited to wild honey which, consisting as it does almost entirely of mono-saccharide (grape sugar and fruit sugar), is very easily disposed of by the digestive organs. Nowadays the less digestible cane sugar (which is a di-saccharide) is very largely consumed in the undiluted state, in which it is apt to set up disturbance. When, however, it is obtained by chewing the sugar cane it is diluted both by the water in the cane and by the saliva and I should like to see children obtain most of their cane sugar in this way.

The consideration of the conditions obtaining for pre-agricultural man not only strongly suggests that the young human of to-day should be given starch in very moderate quantities up to the twelfth month, but it points an even more important lesson—viz., that this substance should be given *not, as is the custom, as liquid or pap but in a form compelling vigorous mastication*, for it is certain that early man from the time he emerged from the ape till he discovered how to cook his vegetable food obtained practically all his starch in such a form; it cannot too often be repeated that uncooked starch in the natural state, locked up as it is in chambers of indigestible cellulose, has no nutritive value; these chambers need first to be broken up by prolonged and energetic chewing, and in this way *much or most of the starch is converted in the mouth into dextrines and maltose, very little passing into the stomach in the crude state* to set up disturbance in that organ and later in the bowel. If it is given as liquid or pap it will pass down as starch into the stomach, while if it is administered in a form which obliges the child to chew it properly, not only will the jaws, the teeth, and the gums obtain the exercise which they crave and without which they cannot develop normally, but the starch will be so thoroughly insalivated that much of it will be converted within the mouth into maltose. How foolish to upset the child's digestive system by deluging it with liquid starch and then to endeavour to correct matters by giving the malt extract which the child can and should himself manufacture within the laboratory of his buccal cavity.

Clearly, then, the child should make his first acquaintance with starch, not in the form of a liquid or pappy patent food, but in a solid and somewhat tough form. The best means of achieving this end is occupying my attention and I hope soon to publish the results of my investigation. Meanwhile, I would point out that hard, well-baked crusts constitute a convenient form in which to administer starch to children. A piece of crust may be put in the oven and rebaked; this not only hardens it but helps to convert the starch into dextrine which is a stage on the road to maltose. If the crust be then cut into a suitable shape and spread with bacon fat or fresh butter it constitutes a most agreeable morsel. Later we may give hard plain biscuits. The same principle should be acted upon during later childhood and youth: we should always give, as far as possible, the starch in a form compelling abundant mastication. Loaves should be shaped so as to give a maximum of crust and a minimum of crumb and should be baked hard. Such loaves are quite as nutritious as the ordinary ones and much more digestible, containing as they do an abundance of dextrine and not a little maltose, and compelling efficient mastication, especially if eaten, as they should be, without any fluid. A lady who has the catering for a large number of girls gives the bread in this way and she tells me that there is keen competition for the most crusty portions.

I do not say that starch in the liquid and pappy form should find no place whatever in man's dietary at the present day, for this would imply the prohibition of porridge, boiled potatoes, milk puddings, and the like. We cannot put back the hand of time and return to the food of our primitive ancestors, nor is it desirable that we should, but we can, at least, arrange matters so that a large proportion of the starch we consume shall be in a form inviting mastication, such as crusts, stale bread, stale cake, biscuits, and so forth. The less children eat of pastry, or, indeed, of any luxurious foods, the better; if brought up on a healthy dietary and under healthy conditions generally they will relish their simple fare more than the choicest dishes of the epicure. I do not, I say, object to the child consuming a certain proportion of starch in the liquid or pultaceous form, for if by bringing him up on a rational dietary his instinct to masticate be afforded due opportunity to develop he will be likely to subject even soft vegetable food to something like adequate mastication; this will tend to mitigate the evils associated with such food, not only by facilitating the digestion of starch, but by flushing the mouth and promoting the health of the teeth and buccal mucous membrane.

The question how far children should be allowed to crack nuts may here be considered. If the child has been brought up on pappy food, and has in consequence brittle and ill-developed teeth, the cracking of hard nuts will be likely to injure them, and this is *a fortiori* true if any of the teeth are carious or "filled." And not only nuts but hard food of any kind, such as ship's biscuits, may in these circumstances injure the teeth, as many of those who went through the recent South African campaign can testify. But if, on the other hand, the child has from the beginning been fed on coarse hard foods, so that the teeth have been allowed to grow dense and strong, no harm is likely to ensue from cracking such nuts as filberts and Spanish nuts. If a squirrel or a monkey weighing a few pounds can do so with impunity surely the young human should be able to also. The cracking should, however, be done by the molars, while such hard nuts as Brazils had best not be tackled at all.

Animal food does not need the same amount of mastication as vegetable food since it is not digested in the mouth, though some contend that the mixture of proteid with alkaline saliva facilitates its subsequent peptonisation. Cooked animal food is, however, all the better for some mastication owing to the coagulation of the proteids, and in order to insure the efficient mastication of meat, fish, and poultry Dr. Sim Wallace recommends that they should be given in large pieces cut thin. "Flat pieces about one inch square generally *necessitate* a certain amount of mastication. It is difficult to swallow large flat pieces of meat without mastication, but when finely minced little or no mastication is called forth." The younger the child the more underdone should the meat be.

EXAMINATION OF THE MOUTH AND ADJACENT PARTS.

If a child be brought up on the lines indicated and under healthy conditions generally it is tolerably certain that the maxillary apparatus will develop normally, that the teeth will be strong and well opposed, and show little tendency to disease; but inasmuch as the methods advocated are but seldom put into practice disorders of the teeth, more especially caries and irregularities, are common, and hence with a view to promote more efficient mastication it is always advisable to examine our patient's teeth.

Each individual tooth should be inspected in a good light for the presence of caries and careful note should be taken of the "bite," a normal bite implying not only a proper opposition of the two rows of teeth but the capacity of the lower ones to move freely across the upper; mere vertical movement of the mandible does not constitute efficient mastication. In this connexion it must not be forgotten that an unopposed molar is useless for purposes of mastication, and it is by no means rare to find in a mouth several sound unopposed molars which are for this reason absolutely functionless. Nay, more than this, it may happen that teeth, perfectly sound ones, too, far from helping, may actually interfere with mastication; thus among the poor we sometimes find all the teeth gone save the upper canines and the lower incisors, and the teeth and gums being alike unable to come into contact nothing worthy of the name of mastication is possible; it would be far better to be without any teeth whatever, for the toothless gums would then be permitted to come into contact along their entire extent, under which condition they gradually harden and come to be quite efficient grinding agents.

Next the gums, the alveoli, and the roots of the teeth must be examined, especially for the presence of erosion, tartar, and *pyorrhœa alveolaris, this latter condition being evidenced* by the welling-up of pus upon pressing the gums against the sides of the teeth.

If our examination of the mouth discloses anything likely to interfere with mastication the aid of the dentist should at once be sought, but every physician should be so far acquainted with disorders of the teeth as to be able to say, in the majority of cases, at all events, when this is necessary. I am convinced that far more illness than is generally supposed is attributable to dental defects and this even among the more leisured classes. With regard to pyorrhœa alveolaris, it has to be remembered that it not only does harm by causing loosening, lengthening, and shedding of the teeth and thus interfering with mastication, but also by contaminating the stomach and the blood and thus upsetting the digestion and causing constitutional diseases such as anæmia and arthritis; and inasmuch as poisonous discharges from the nose, the naso-pharynx, the pharynx, and the tonsils may act in a similar way, these parts also should be inspected in connexion with the examination of the teeth In the dust-laden atmosphere of towns they are very liable to disease and even when healthy are necessarily dirtied; some go so far as to advise all town dwellers daily to wash out the nasal passages and to gargle the throat, but whatever [illegible] certain that under existing [illegible]s are needed in order to keep [illegible] teeth clean. [illegible]hen man fed on raw food this was not necessary, the food itself and the copious flow of saliva induced by prolonged mastication effectually cleansing these parts; but, under present conditions, food tends to remain within the mouth, especially between the teeth and in their crevices and therefore special means are needed to remove it. This is done by "cleaning the teeth" and by rinsing the mouth.

The tooth-brush.—Probably the ideal method of cleaning the teeth is that adopted by many primitive and not a few semi-civilised peoples—viz., rubbing them with a twig of wood which has been teased out at one end so as to form a sort of brush by means of which the teeth can be burnished and food dislodged from them. The modern tooth-brush requires to be used with great caution as it is capable of doing much harm, not only by removing the mucoid film which according to Dr. Wallace protects the teeth from corroding agencies,[2] but probably also by injuring the edge of the gum and the neck of the teeth and thus setting up the condition known as "erosion." Certain it is that some of the best sets of teeth I have encountered have been wholly unacquainted with the tooth-brush. In any case the brush should be employed with great care; it should be soft and should always be drawn away from the gums both on the inner and outer aspect of the teeth towards the biting surface as well as across the latter, never tranversely across the outer surfaces, as so frequently is done. The object of these procedures is to dislodge any particles of food that may have collected between the teeth or in their crevices. For this purpose the tooth-pick may also be employed judiciously. In order to render the enamel of the teeth white it is better to rub each tooth carefully with some soft material, such as chamois leather, rather than to scrub them with a brush. Tooth-powders should not be used as a matter of routine but only occasionally and for appearance rather than for cleanliness and should consist of some simple non-irritant material. Antiseptic powders and washes are to be scrupulously avoided, for it is neither desirable nor possible to render the buccal cavity aseptic; myriads of bacteria flourish within it, many of which play a useful part as scavengers. The time of all others for cleaning the teeth is just before going to bed, so that the food shall not be allowed to decompose in the mouth during the night. There will then be no need to use the tooth-brush in the morning.

Rinsing the mouth.—The mouth should be rinsed out as a matter of routine after each meal and on rising, and care should be taken to do this before the early cup of tea so as not to contaminate the stomach with the buccal secretions which have accumulated during the night. Inasmuch as raw vegetable food has a cleansing effect on the teeth it is often a wise plan, especially in the case of children, to finish a meal with some kind of fruit, such as an apple or an orange. It hardly seems necessary to insist upon the necessity for keeping all artificial dentures thoroughly clean.

AN ANALYSIS OF THE VACCINATION STATISTICS OF THE METROPOLITAN ASYLUMS BOARD FOR 1901 AND 1902.

BY J. E. SANDILANDS, M.D. CANTAB.,

LATE ASSISTANT MEDICAL OFFICER ON THE SMALL-POX SHIPS, DARTFORD.

WITH the appearance of the annual report of the Metropolitan *Asylums* Board for 1902[3] access is given to *one of* the most valuable contributions to the question of vaccination and small-pox hitherto published. Unfortunately, those who will have the leisure to study the figures set forth by the statistical committee must of necessity be few and an attempt has accordingly been made to summarise in the following paper the facts which everyone is anxious to know but which everyone has not the time to seek out for himself. For this purpose the figures for 1901 and 1902[4] have been combined and a total of 9659 cases of small-pox has in this way been obtained for analysis. The age incidence and mortality in unvaccinated cases are too familiar to need more than a passing comment. The incidence in early life is overwhelming and the mortality at all age periods is high, varying between 20 and 50 per cent. The figures in the annual report show the unvaccinated cases in the late epidemic to have followed this general rule. The incidence of vaccinated cases is small in early life and reaches its maximum in the third decade, whilst the mortality increases with each decade, reaching to about its maximum in the group of confluent vesicles, as would be conferred by making four separate scarifications over smaller areas. Explanations are a source of comfort to those who can accept them and of vexation to those who cannot. In any case they are of secondary importance and if the public can be induced to recognise that four large scars are associated with a higher state of protection than one small scar and to condemn the practice of vaccination by less than four insertions they need not be burdened with the explanation of these mysteries.

---

[2] This film can be felt by the tongue as a somewhat rough covering which gives place to a smooth surface after the use of the tooth-brush.

A NOTE ON COLOTOMY AND COLECTOMY.[1]

BY F. T. PAUL, F.R.C.S. ENG.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY; PROFESSOR OF MEDICAL JURISPRUDENCE AND LECTURER ON DENTAL ANATOMY AT UNIVERSITY COLLEGE, LIVERPOOL.

SOME ten years ago the value of colotomy in cases of rectal cancer was discussed at this society. At that time several of the most experienced members of the Liverpool Medical Institution were only prepared to advocate it as a means of giving relief when the most urgent and distressing symptoms were present. I remember that it was classed with gastrostomy and gastro-enterostomy for malignant stricture as dangerous to life and as producing other ills almost, if not altogether, as unpleasant as those which it was designed to relieve. We may truly say now that we have changed all this, not only for colotomy, but for gastrostomy and gastro-enterostomy as well, but especially as regards colotomy. And it is felt now that it is right to recommend the latter in any case of rectal cancer unsuitable for excision in which distressing symptoms are present or are indicated; indeed, enthusiasts (and I may include myself) for high operations in extensive rectal cancer seem to be inclining again to substitute a permanent iliac colotomy for these very serious and wide operations, or to do it as a preliminary, and so to lessen the risk of the subsequent proceeding.

Modern colotomy has unquestionably gained in favour, and this gain is due to two causes: (1) lower mortality and (2) improved artificial anus. The latter has, I consider, been the more important factor, for when a patient is labouring under a mortal disease it is more a question of comfort and the capacity to continue his daily avocation than the simple prolongation of a more or less miserable existence. In the discussion to which I have referred it seemed to be strongly felt that the discomforts of the artificial anus were frequently as great as those of the malignant ulceration. The want of control over the evacuations, the dependence upon assistance after each movement of the bowels, and the rather frequent occurrence of prolapse certainly rendered the life of a colotomy patient a far from happy existence. Now usually very fair control is established in most cases, and prolapse hardly ever occurs, whilst with an anterior opening the patient can attend to himself—a condition of independence which is greatly appreciated by the good, hopeful, deserving class of patients. I have no sympathy with those who give in. It is the duty of all of us, not only to live, but to work as long as we are able, and it is as we all know quite possible for any colotomy patient not otherwise disabled to do his daily work, whether manual or sedentary, when the artificial anus is a good one.

Amongst the various suggested methods for performing iliac colotomy it must be conceded that, at any rate in England, Cripps's method is that which has met with most general favour; indeed, Mr. Herbert Allingham, who advocated a rival method, has of late accepted the former except in cases in which the sigmoid mesentery is long and the patient may be expected to survive a considerable time. In my judgment Allingham's present position is a wise one. The variability of the anatomical conditions of the sigmoid flexure is such as to render it impossible that the same method of dealing with it can be the best for every case, and it certainly seems the fact that when the flexure is voluminous and its mesentery long Cripps's method, however carefully accomplished, is very likely to be followed by a moist patulous anus, over which it is difficult to create any control and through which prolapse of bowel is very probable. Allingham's procedure is undoubtedly rather more severe, but it results in an excellent orifice and the increased comfort when the operation is properly indicated is well worth the increased risk. The results desired from a colotomy are (1) relief, (2) safety, and (3) comfort.

First, as to relief. In cases of obstruction immediate relief is urgent. This perhaps applies to 20 per cent. of the cases; less when the disease is in the rectum; but more when it is in the colon. When the operation is undertaken with the necessity of giving immediate relief I urge the glass-tube method, and I may do this with more confidence now than in 1891 when I first introduced it, since not only has my personal experience of the method been fairly considerable since that time, but I gather that it is now generally practised in these circumstances. Cripps's and Allingham's operations do not provide for the immediate opening of the bowel; but I have practised both operations many times, and in all sorts of circumstances, in conjunction with the glass tube, and have no reason to think that these operations are rendered appreciably more dangerous thereby. If this experience is correct and it is true—as I believe it to be—that opening the bowel at the time of the primary operation by the glass-tube method does not appreciably increase the risk to life, then it is certainly a desirable addition in most cases, for not only is it convenient that the bowel should be open and free for the passage of flatus or fæces, but the wound in the abdominal wall may be smaller, a point of some importance, and the operation is completed at one sitting. There is no occasion for the subsequent incision and later paring of the mucous membrane required in Cripps's operation, and there are no subsequent clamping and removal of bowel as in Allingham's. I therefore distinctly recommend that in performing either of these operations the glass tube should be used and the bowel opened at once, whether obstruction is present or not.

Next as regards safety. When the patient is in an exhausted condition Cripps's operation with or without the tube should be selected, as the removal of bowel, especially if the mesentery be thick, increases the risk. Should obstruction be present in introducing the tube every precaution must be taken to avoid leakage. In all cases both the bowel and the tube should be attached to the abdominal wall, the bowel by at least two green-gut sutures connecting it with the deep muscular aponeurosis, and the tube by passing its silk ligatures through the skin and knotting them. Then if the tube is accidentally dragged on it is well and safely anchored and when it comes away, if the adhesions between the bowel and the parietal peritoneum are weak, they are backed up by the green-gut sutures.

As regards comfort the essentials are: (1) a high operation, a small wound, and opening the highest portion of colon available, as recommended by Cripps; (2) the formation of a good spur; (3) embodying the principle of Allingham's operation whenever the sigmoid flexure is voluminous and its mesentery long and the patient sufficiently robust to make this wise; and (4) the use of a good plug and the cultivation of a regular habit of bowels. After various trials with trusses and belts I have come to use an aluminium mushroom-shaped plug. The plug or stalk is slightly bulbous and long enough to pass through the whole depth of the abdominal wall. The head or flange is oval-shaped and wide; it is slightly concavo-convex to fit the abdominal surface. A single layer of soft lint with a hole in the middle for the stalk is placed under the flange and a good pad of cotton-wool above it, the whole being kept in place by a narrow abdominal belt, such as I use after appendicectomy. This is the cleanest and by far the most comfortable and effective apparatus I have yet tried.

In 1898 I designed an operation to give better control over the artificial anus. It involved using Madelung's method of closing and returning the rectal end of the bowel into the abdominal cavity, whilst the upper end was brought out at a distance, after having passed between the muscles—in fact, after the principle of Hahn's or Frank's gastrostomy. The operation was effective but dangerous. It was unnecessarily severe and in passing the bowel between the muscles septic infection was liable to occur. For these reasons I soon abandoned it and I think now that sufficiently good control can be obtained by ordinary methods.

The details of a colotomy by the glass-tube method are as follows. 1. The incision is made in accordance with accepted principles, but may be smaller, that is from one and a half to two inches, according to the condition of the abdominal wall and the bowel. 2. If the mesentery be very short the bowel is firmly drawn out and a running suture of medium thick silk is inserted round an oval area involving

---

[1] A paper read at the Liverpool Medical Institution on Feb. 12th, 1903.

as much of the circumference of the bowel as possible, so as to insure its posterior wall being well brought up to the surface to form a good spur. The inclosed area is then gripped with two catch forceps, incised, the tube plugged with wool inserted, and the ligature tied. A second silk ligature is then simply tied over the first to render it more secure and is knotted on the opposite side of the tube. Two or more green-gut sutures are next passed between the outer coats of the bowel and the deep tissues of the wound, and finally the ends of the silk ligatures are passed through the skin and tied so as to secure the tube in case of roughness or accident. *Usually the wound is too small to need any* further sutures. The parts are well powdered with iodoform and dressed with gauze and wool as usual, and a binder split to transmit the tube is firmly applied. If the bowel is empty a light plug of wool is kept in the tube. If loaded with formed motion a sponge bag containing some iodoform wool or wool sprinkled with eucalyptus oil is attached. If with loose motion a short piece of Down Brothers' thin wide indiarubber tubing is attached to the glass-tube and allowed to fall into a basin at the patient's side. 3. If the mesentery be long and the patient in good condition the loose loop of sigmoid flexure should be drawn out, the mesentery ligatured separately, a large tube fastened into the top end and a small one into the bottom end, and then all the redundant bowel cut away. It is better not to ligature the mesentery together with the bowel to the tubes, as unless the grip is very tight some of the vessels are liable to retract and smart hæmorrhage may result. It will be found much safer to tie the mesentery in two or three sections by itself. When the sigmoid mesentery is of medium length either Cripps's or Allingham's method may be used; but in all cases when doing Cripps's operation care must be taken to insert the tube into the highest portion of bowel which can be brought out of the wound and to include the whole, or almost the whole, circumference of the bowel. 4. Usually on the fifth day the tube is ready to come away. When this is the case, indicated by leakage beside the tube, the silk sutures are cut and it is withdrawn. 5. Subsequently the patient is kept in bed, the motions being passed into the dressings until the wound is healed, when the plug and belt are worn.

Colotomy in other regions.—For some time I maintained it was our duty to perform colotomy as low down in the bowel as we could consistently with being well clear of the disease. Now I am inclined to think that there are only two good colotomies—sigmoid and transverse. In the few cases in which I have had to do the latter it has answered very fairly well—not so well as the sigmoid but decidedly better, I consider, than the lumbar operation. Right iliac colotomy I do not like at all; the motions are liquid and quite uncontrollable. I never do it except in cases of obstruction and then only in the hope and expectation that subsequent enterectomy or short-circuiting will be possible. When the cæcum is opened only a small tube should be used, one of from half an inch to five-eighths of an inch in diameter being sufficient.

It has been said that subsequent trouble will result if either the sigmoid flexure or cæcum are opened and attached in the middle line. I have had to do this occasionally and in practice no inconvenience has resulted. This position would never be chosen, but at any time there may be urgent reasons why it should be adopted.

The operation of colotomy is so closely associated with that of colectomy that I can hardly treat of one without reference to the other. Often when colotomy only is intended before exploration colectomy is ultimately undertaken, or the reverse may be the case; whilst, as I have stated, it is no unusual thing for me to cut away several inches of colon with the simple object of improving the character of an artificial anus. When, however, the original intention is colectomy there are a few additional points which need careful consideration. The chief of these are the exact location of the disease and the restoration of the continuity of the bowel.

It is a great misfortune that malignant disease of the colon is so very undemonstrative in early stages. Recently in one week I was asked to see three cases all of which were too late for operation—that is, in all the tumour was hopelessly adherent to neighbouring important structures. This form of cancer is one of the least malignant with which I am acquainted, and could one obtain the cases early enough, as happens more frequently in the rectum, the results would be excellent. In its first stage, however, it apparently sets up no recognisable symptoms and I have no doubt it often exists for several months or a year or two, according to the type of the growth, before any evidence whatever of its presence is afforded. The earliest symptoms are frequently those of intestinal indigestion, brought about by some difficulty in the contents of the bowel passing the diseased part; they are flatulence, slight colicky pains, some distension, and irregularity of the bowels. In other cases there are no obstructive symptoms at first, but mucus and perhaps blood appear in the motions. At a later stage some obstruction is usually present, characterised by *increasing constipation with attacks of colicky pain. Loss* of flesh occurs and ultimately a tumour is discovered in some cases, whilst in others the surgeon is called in because complete obstruction has supervened. The clinical details are influenced by the character of the growth. From 35 to 45 or 50 years of age the disease is generally of the fungating type and produces more of a tumour than an ulcer. In these cases there is often no obstruction but plenty of mucus and blood in the motions. The abdomen is not distended and if carefully palpated the tumour might usually be discovered much earlier than it is. Still, one must bear in mind that the patient suffers little and frequently makes no complaint until it is too late. Indeed, it is sometimes the discovery of the tumour by the patient himself that leads him to consult his medical adviser. From 50 to 70 or 80 years of age the growth is usually of the chronic ulcerating type, producing the ring stricture. In these cases the symptoms are almost entirely due to obstruction, which in the end generally becomes complete owing to the narrow lumen at the strictured part (often only transmitting a No. 10 catheter) becoming blocked by some undigested substance in the fæces.

When distension is absent a tumour is often present and in this way the disease is usually located in the younger class of patients; but after obstruction has once set in it is rare to be able to detect a lump and one must be guided in other ways in locating it. Probabilities are of no help. The sur[illegible] ause [illegible] In [illegible] ddle line should be the practice. The best aids to diagnosis are the capacity of the bowel below the stricture, the condition of the cæcum and colon as made out by percussion and palpation, and the evidence afforded by pain and peristalsis. *The patient is often quite conscious of the site of the stricture*, having many a time felt a colicky wave of peristalsis pass away at a particular spot with a gurgling sound as gas and liquid were forced through the stricture. And when the bowel is much hypertrophied one may see the peristaltic wave gather and run on until it comes to a stop at the stricture. The enema, too, is a great help when the disease is low down. As the result of experiment on the dead subject I believe the bowel will hold something like two pints with an obstruction in the sigmoid flexure, but in actual practice one finds that from half a pint to a pint is all that is tolerated, usually the former, and that it is returned at once without motion. In these circumstances the tumour is in the most favourable place for operation. When it is higher up large quantities of injection may be introduced and retained. The operator has then to be guided chiefly by palpation and percussion of the regions of the large bowel and if nothing definite can be made out a middle-line exploration should be undertaken.

When the tumour is located it must be freely exposed, and if suitable for removal the mesentery in connexion with the part involved is carefully divided so that the diseased coil of bowel may be brought out of the abdomen. The subsequent steps of the operation depend upon the mode of union to be attempted, and in regard to this I continue to differ strongly from those who consider primary end-to-end union by suture or button the proper course to adopt as a routine practice. That it is the neatest and most satisfactory to the surgeon when the patient lives I do not doubt; but it is certainly more dangerous without ultimately being at all more efficacious than when the ends of the bowel are brought out and the continuity of the canal is subsequently restored. When this is done it is a rare thing to lose a patient who is not at the time of the operation seriously depressed as the effect of several days' obstruction of the bowels. In this connexion I may as a surgeon warn my medical friends that a patient after ten days' obstruction in the lower bowel is in much worse case than his pulse and appearance seem to indicate. The surgeon is asked to perform colotomy in these circumstances with the assurance that the patient is in excellent condition. It is quite true that he is fit to bear the operation; but when he dies a few days later death should be ascribed to the absorption of toxins, which is the cause of it, and not to the operation which has had nothing to do with the unfortunate result.

In 1892 I commenced operating by bringing out the ends of the bowel and after ten years' experience am strongly confirmed in my opinion that it is the right thing to do. I know nothing against it except that the patient has the discomforts of an artificial anus for a few weeks and the course of the case is prolonged by about a month—small evils compared with the gravity of the disease and the risks of end-to-end union. It has been suggested that stricture might result from incomplete removal of the spur, but such has not proved to happen in any of my cases. After dividing the mesentery the subsequent steps of the operation are of the simplest. The tumour being well drawn out of the abdomen, the ascending and descending portions of the colon are made to lie side by side, like the barrels of a double-barrelled gun, in which relationship they are lightly sutured together for quite three inches inside the abdomen. Outside the abdomen a colotomy tube is ligatured into the upper end and a smaller tube into the lower end, when the diseased part is cut away, of course quite bloodlessly. A few fine sutures may be used to attach the bowel to the parietal peritoneum at the bottom of the wound, and if the incision has been long its ends are brought together with fishing-gut sutures.

In many cases the operation is very little more severe than colotomy. Five or six days later the tubes separate, and at the end of three weeks, as a rule, the carefully prepared spur may be clamped. I once had a warning that this should not be done too hastily. After complete obstruction the bowel is liable to be in a very septic and irritable condition, and so long as the spur feels thick and hard to the finger I believe it to be unwise to apply the clamp. As a rule it is supple throughout, and in these circumstances may be clamped at any time. One clamping is very likely to be insufficient, and if there is a considerable ridge still apparent at the bottom the clamp should be applied again. It need not be kept on each time until it comes away, as its work is thoroughly effected in 48 hours, when it is probably safer removed than left *in situ*. As soon as the spur is completely destroyed the artificial anus is closed. The entire operation has been completed in 24 days; but usually from six to eight weeks must be allowed for it.

In cases of malignant disease of the colon in which the mesenteric glands are involved I used to give a most depressing prognosis, but have now met with a few in which such a prognosis was not justified. About four years ago I removed a cancerous tumour of the sigmoid flexure, together with several enlarged glands in the attached portion of the mesentery. The glands were as large as Barcelona nuts, and I thought the case quite hopeless; nevertheless, she is now, four years after the operation, in excellent health and still continuing her vocation as a domestic nurse.

Two years ago I removed the cæcum and lower part of the ileum from a man, aged 38 years, for a soft malignant growth. The lump was of the size of a fist and several glands were enlarged, one measuring one and a half inches in diameter. Here, again, I gave a bad prognosis. He recovered well from the operation and a year later was in such excellent health that his medical friend, Dr. F. Heatherley, refused to countenance any longer a pessimistic outlook. He came to me and said, in effect, "Look here, you must do something for this fellow. He must not be condemned to die in this sort of way. How about the x rays?" Well, I do not think we have at present any information which warrants us to suppose that the x rays would influence the course of such a case, so I suggested that if the patient was willing to lie up for a month I would explore the abdomen, ascertain what the present condition was, and do what seemed to be best in his interests. This was decided on and one day, after quite half an hour's exploration, I succeeded in discovering and extracting one small gland of the size of a split pea which on microscopical examination showed no malignant change. Another year has passed and the patient is still as well as ever—so well, in fact, that he at once agreed to come here with Dr. Heatherley to show us that we know almost as little about the prognosis as about the treatment of cancer.

Liverpool.

CAN THE RESPIRABLE PRODUCTS OF HUMAN WASTE HINDER DEVELOPMENT AND LOWER VITALITY?

BY JOHN HARTLEY, F.R.C.S. ENG.,
HONORARY SURGEON TO THE DARLINGTON HOSPITAL; LATE SENIOR DEMONSTRATOR OF ANATOMY, MIDDLESEX HOSPITAL MEDICAL SCHOOL.

THE following premisses will scarcely be denied. 1. That the infinite precautions for the due excretion of waste products observable in the economy constitute *primâ-facie* evidence of the poisonous nature of such products and that any serious or prolonged interference with the functions of any one of the great channels of exit—lung, kidney, bowel, or skin—is invariably followed by death. 2. That the blood current forms the chief medium of dissemination for systemic poisons. 3. That poisoning by the lungs may be at least as rapid and effectual as that by the alimentary canal, as witness the action of the so-called general anæsthetics, of sulphuretted hydrogen, carbon monoxide, and the like. 4. That the common use of the term "insanitary" as applied to ill-drained, ill-ventilated, and crowded dwellings is evidence of a consensus of opinion that the air of such dwellings has a definite influence in lowering vitality. Probably none of the foregoing statements will be seriously questioned, but when one approaches the crux of the matter and asks why is an insanitary dwelling insanitary, one receives answers such as the following: "Absence of sunlight," "absence of ozone," "absence of oxygen," "presence of organisms," "overcrowding."

If one ventures to suggest that the volatile products of animal waste may constitute deadly toxins and that such may find a very direct road to the tissues through the lung, one is met by incredulity. I find no suggestion in medical literature that such a process may be common. Volumes, and most useful ones, have been written on the subject of poisoning through the alimentary canal, as well as larger, and perhaps less useful, volumes on diet and drink. Even the theory of auto-intoxication (apparently a kind of unreasonable tissue-cussedness) has been dragged into account for the phenomena of lowered vitality. A girl has pale cheeks, damp cold hands, feeble pulse, and poor appetite, and she keeps them in spite of our drugs. No organic disease is to be found. Is one to be content with a diagnosis of constitutional debility or even auto-intoxication? No doubt the former is true so far as it goes. The predisposing cause must be undoubtedly within the girl, but the determining cause, the active poison, as I believe, starts outside the girl and, I think, usually enters by the lung. Here one, of course, is met by the argument, "But all the rest of the household may keep well under precisely similar conditions." To this there is the obvious answer: a single glass of whisky will make some persons drunk; a dose of poison harmless to the many may be harmful to the few. Medical opinion seems to hover on the edge of this question in a curiously uncertain manner. Its discussion is rarely or never attempted. Yet if there is anything in the view that the volatile products of animal waste constitute a poison readily absorbable by the lung, one can scarcely conceive of any more important issue, and it is solely in the hope of provoking some discussion of the subject that I venture to air my own crude ideas.

If we trace the path of a soluble body in its passage from the alimentary canal to the tissues and compare it with that of a volatile toxin starting from the alveolus of the lung, we see that even at the start the former may be handicapped by the possible action of the digestive ferments, then, according to its nature, it must run the gauntlet either of the epithelial cell or of the capillary of the liver guarded by the hepatic cell, and lastly it must face the ordeal of the capillary of the lung before reaching the tissues. In the case of the volatile toxin approaching by the lung the only barriers between it and the blood are the thin cellular walls of the air cell and capillary specially designed for the transmission of gases. The poison enters just at the moment that the blood is undergoing its final purification previously to being distributed to the tissues. From the capillary of the lung to the capillary of the tissue the road is clear, all is main line and "la Grande Vitesse." There can be no doubt that the lung provides the royal route to the tissues. It is surely for this reason that we have long given up trying to drug our patients by the stomach before operating and now give our general anæsthetic by the lung. We choose a highly volatile toxin and in less than two minutes in skilful hands the patient is unconscious. The route then is emphatically "all right." If the inspired air contain sewer gas, or respiratory products, the blood is started from the lung *en route* for the tissues actually loaded with imported waste.

As to the *modus operandi* of the poison—if poison it be, one needs to go no further than the out-patient department of a large hospital; the well-remembered smell gives assurance that there is no lack of the volatile products of human waste. Most assistant physicians or surgeons will bear me out in the assertion that a long afternoon in a crowded and badly ventilated out-patient room is fatiguing; to some very exhausting. To the most enthusiastic even good cases seem to be a little less interesting, and even good students are a little less attentive, towards the end of the afternoon. The looker-on without duties to perform experiences the same fatigue. There can be no question but that the sense of fatigue both of body and mind is largely due in some way to the foul atmosphere. The greater the crowd and the fouler the atmosphere the greater the fatigue. I suppose it is still generally accepted that fatigue of muscle is coincident with accumulation of its waste and may be partially removed by lessening this accumulation—as by massage. It would seem that other people's waste is quite as capable of causing fatigue as our own. But besides the subjective sensation of fatigue objective changes are usually visible. The face becomes paler and a shade blue and pinched. If anyone doubts this statement let him contrast the aspect of the congregation of any fashionable church or chapel at the end of the service with that at the beginning. In most cases half an hour in the open air and a meal will remove the greater part of both objective and subjective effects. The conclusion is forced upon one that the condition is mainly circulatory.

Is this condition central or peripheral? Faintness, palpitation, and the like are relatively, though by no means actually, uncommon, and, as a rule, the chief inconvenience felt is fatigue. It is apparently the periphery that mainly suffers. Now putting aside the heart the arteriole is, so far as we know, the only portion of the blood-carrying tube the lumen of which is under the direct control of drugs; we can certainly dilate it at will either through the stomach or the lungs. We have, therefore, presumptive evidence that, granted the occurrence of pallor among persons temporarily exposed to an atmosphere largely fouled by human waste, contraction of the arteriole is the most probable determining factor. We urgently need the intervention of the test of scientific experiment to put this to the proof. We know that obstruction to arterial flow is a common cause of passive hyperæmia. Contraction of the arterioles and consequent dilatation of the venules would account for the pallor and blueness noted above; but, besides this, contraction of the arterioles means sluggish capillary flow, lessened supply of nutriment and oxygen to the tissue cell, and slower removal of waste—of waste, be it remembered, already reinforced by the foreign supply brought in from the lungs. The metabolism of the tissue cell thus starved and choked must be lessened and its vitality and functional activity must be impaired so long as the action of the poison continues.

For the sake of argument let it be conceded that some such action on the peripheral circulation may explain the undoubted effects of temporary exposure to an atmosphere highly charged with waste products and let us see whether such action, if indefinitely prolonged, might account for the condition of those who have habitually inhaled such an atmosphere. Turning, then, to the occupants of the out-patient waiting-room or to the population of the slum outside I think that we shall hardly be able to resist the conclusion that there are certain peculiarities in the aspect of these people which are far less evident in any gathering of country folk. The women and children of the out-patient room or the slum provide, perhaps, the most typical instances. The most casual observer will note that rosy cheeks are rare and that pallor is usual—a sallow or blue tinge being often combined with the pallor. Most of the women look older than their years; those above 30 years of age are either gaunt and haggard or flabbily fat and in the older ones pigmentation and coarseness of skin are almost universal. There is in many cases an appearance of inertness and lack of vitality as remarkable as it is difficult to describe. On closer examination feeble hearts and "inadequate" kidneys are found to be common. Among the children the muscular development is, as a rule, poor, especially as regards the lower limbs. Shapely, well-developed legs and feet are quite uncommon and a large proportion show signs of rickets. I hope that this description will be admitted to be fair. From the nature of their surroundings it can hardly be seriously questioned that the majority of these people habitually breathe air fouled by the volatile products of human waste. They are, I have good reason to believe, at least as well fed as the average of the country poor.

We know that induration from the growth of white fibrous tissue and pigmentation are the two most common changes brought about by repeated or prolonged passive hyperæmia. These older women show both changes in the coarsening and pigmentation of their skin to a marked degree. Most of them will tell us that they cannot walk fast or exert themselves much, that they are easily tired, and short of breath. And we can scarcely help admitting that lessened metabolism and resulting degeneration of protoplasm are the causes of the flabby muscles and feeble movement which are so common among them. In many of them the first heart sound at the apex is feeble, though there is usually no murmur, while there s strong ground for suspicion that degeneration has begun in the heart wall. The kidneys are probably "inadequate," in other words, fibrous, and fatty change is present in them.

> "The narrows measure the river's flow,"

and it seems difficult to avoid the conclusion that permanent narrowing of the lumen of the arteriole, causing as it must do shortage of arterial supply, sluggish capillary and venous current, and therefore slow removal of waste, must inevitably lessen the metabolism and eventually cause the destruction of the starved and waste-ridden tissue cell. And be it remembered, even the meagre supply of arterial blood thus delivered is not a pure one. It has been fouled already in the pulmonary capillary by the immigration of foreign waste. It so far resembles the blood in the descending aorta of the fœtus, distributed to the lower limbs with results known to every student.

I have spoken of permanent diminution of the lumen of the arteriole, for it seems justifiable to suppose that the muscle of its wall will be no more exempt from degeneration than other tissues and that fibrous tissue will gradually take its place. If this be true we have the condition of arterio-capillary fibrosis not as a result of kidney change but as sharing with the immigration of foreign waste the responsibility of its production. But not only do the narrows control the volume of the stream, they also occasion ponding, and this ponding is greater where the fall of the river is less. So the smaller the arteriole and the feebler the heart the greater will be the dilation of the venous system. There will be ponding in the lung, the splanchnic area, and the veins of the pelvis and lower limbs. All will admit that these stout, flabby women are peculiarly subject to bronchitis, to dyspepsia, to varicose veins, and the like.

It is not suggested for a moment that all these changes take place without the intervention of micro-organisms. One can hardly conceive of small-celled infiltration without their aid; but it is suggested that these changes are initiated by volatile toxins absorbed by the lung. As to the undeveloped lower limbs of the children, attention was called many years ago to the length and slenderness of the arteries supplying the cauda equina, and it was suggested that the feebleness of the lower limbs so often observed in fat flabby women might be due to ready interference with the circulation through these long slender arteries. If we suppose the arterioles at the periphery of these vessels to be contracted in children who are habitually exposed to a foul atmosphere we have a condition of circulation which must seriously affect the nutrition and development of nerve, muscle, and bone. There appears to be no reason why the metabolism of the blood-forming tissues should not suffer with the rest. Anæmia is certainly the rule.

Lastly, what happier hunting-ground for bacteria can be imagined than waste-ridden tissues with an impure and restricted arterial supply. The temperature chart of a child suffering from hectic fever due to unremoveable tuberculous disease undergoes an extraordinary change on the child being transferred from the hospital ward to the verandah outside. The hectic fever usually goes as if by magic, often in 24 hours. I can only imagine that, given restored arterial supply and absence of imported waste, the tissues are enabled to withstand even the combined assault of septic and tuberculous organisms. Every hoarding announces the recognition by the masses of our population of the need for improved development and increased vitality. "Frame food," "Force" food, "Phospherine," and countless other forms of profitable philanthropy in the shape of food and drugs are painfully obtrusive. What care we try to take, and very rightly, to prevent the admission of poison to the alimentary canal! How almost laughably anxious are many of us on the question of diet. The law very properly steps in to prevent the adulteration of our food and drink. Analysis fairly runs riot on behalf of our stomachs. But who cares for the purity of the air we breathe unless we happen to be tuberculous?

It is not many years since the House of Commons was gravely informed "against the stomach of its sense" that its air *must* be wholesome since but few pathogenic organisms could be found in it. We flood our rivers and pollute the sands of our health resorts with sewage. Patients not unfrequently tell us that seaside air is "too strong" for them. We ventilate our sewers into narrow streets, courts, and alleys at the road level, regardless of the close-set crowded dwellings so near at hand. As to our living- and sleeping-rooms we most of us ventilate them not at all in the sense of clearing out waste products. One is tempted to wonder if the ills usually ascribed to the high pressure of modern civilisation may not be more justly attributed to the high potentiality of the toxins given off by our crowded populations. This question must from its very nature be either utterly fatuous or of truly vital importance. If a negative cannot be returned to it without a shade of hesitation its discussion is obviously most urgently needed. Discussion, experiment, and research must come sooner or later. We may then get an answer to the query, Can the respirable products of human waste hinder development and lower vitality?

Darlington.

ICHTHYOL IN THE TREATMENT OF PULMONARY DISEASE.[1]

By JAMES BURNET, M.A., M.B., M.R.C.P. EDIN.,
CLINICAL TUTOR, EXTRAMURAL MEDICAL WARDS, ROYAL INFIRMARY, EDINBURGH.

EVER since I became acquainted with ichthyol this substance has had a special interest for me. The more I study it the more distinctly do I understand its therapeutic value and its indications in the treatment of disease. My earliest use of it was in gynæcological cases in the form of tampons, and the success achieved in this connexion encouraged me to make a thorough investigation into its composition. The result was that I turned my attention almost entirely to the internal administration of ichthyol, and more particularly I made a study of its use in affections of the respiratory tract. During the past two years I have devoted much time and attention to the subject and I shall now endeavour to place before you as clearly as I can the results of my observations.

It may be well at the outset to describe very briefly the substance under consideration, and I trust you will not consider me too pedantic in doing so. Ichthyol or ammonium ichthyolate, as it is more correctly termed, is a definite chemical compound. It is obtained by acting upon a crude mineral oil derived from a special variety of bituminous quartz[2] by destructive distillation. This oil is treated with strong sulphuric acid, the product thus obtained being ichthyo-sulphuric or sulpho-ichthyolic acid, a dibasic acid. This acid is in turn neutralised by ammonium and ichthyolate of ammonium or ichthyol is the result. Ichthyol itself is a thick liquid substance of dark brown colour. It has a characteristic taste and odour, the latter being due to the presence of a volatile oil. Ichthyol is readily soluble in water. The crude oil before being acted on by sulphuric acid has the following composition: carbon, 77·25 per cent.; sulphur, 10·72 per cent.; hydrogen, 10·72 per cent.; and nitrogen, 1·10 per cent. Ichthyol itself is usually stated to contain from 15 to 16 per cent. of sulphur.

So far as I have been able to gather, the first mention of ichthyol as a therapeutic agent was by Unna who described its action in certain skin conditions as far back as 1883. It certainly became known to the profession from its use in dermatological and in gynæcological affections. Its internal employment came later and was for some time much praised. At present it is held in high esteem as an external medicament, but I fear that its internal administration is not regarded very favourably by the majority of practitioners. I cannot help thinking that the cause of this is not far to seek. It has very often been given in altogether unsuitable cases and for too short a period, so that with but few exceptions those who have tried it as an internal remedy have failed to derive good results and hence they have unjustly condemned it. I hope to be able to show you that ichthyol is of much service in the treatment of suitable cases of pulmonary disease. I shall first of all present you with a statement of the nature of the cases in which I employed it, together with some account of the results obtained, and then I shall refer at some length to the *rationale* of its action when given internally.

The majority of cases in which I used ichthyol internally were those of pulmonary tuberculosis and consequently my remarks will have very special reference to its employment in this disease. At the same time I have had definite results from its use in two cases of bronchiectasis and also in some cases of bronchitis, acute as well as chronic. Much benefit has also resulted from its use in cases of pulmonary fibrosis of pure type, apart, that is, from secondary tuberculous infection. All my cases of pulmonary tuberculosis were of the ordinary slow, progressive, and chronic type. They were in number 13 and varied in age from 18 to 39 years. As regards sex, four were females, the rest being males. At the commencement of treatment the tubercle bacillus was present in the sputum of each and in some cases was very abundantly present. No other drug save ichthyol was prescribed in any of the cases and the hygienic environment was not always the best possible. All the patients were under my personal observation for at least six months, some of them even for a longer period, so that a definite statement can readily be given as to the benefits derived from this form of treatment. Of the 13 cases referred to 11 were distinctly improved. Only two failed, after prolonged treatment, to show any beneficial results. The two latter were both very advanced cases and in one both lungs were extensively involved. In the remarks that follow I shall therefore confine my attention entirely to the results obtained in the 11 successful cases and shall disregard the other two entirely. A summary of the results obtained at the end of each month may be put down as follows. At the end of the first month of treatment I found that in six of the cases the cough was less harassing, while the other five showed no marked improvement. At the end of the second month every one showed distinct improvement as regards cough, while in eight the expectoration was either appreciably less in amount or both less in amount and easier of expulsion. Only one of the cases showed absence of night-sweating, all the others still complained of it to a greater or less extent. By the end of the third month seven of the patients were so far improved that no night-sweating was to be noticed. At the end of the fourth month of treatment night-sweating was entirely absent in every case, while only a slight cough remained. The expectoration had now become very scanty in amount and that chiefly in the mornings. Its expulsion was now quite easy and caused no distress as it formerly had done. Towards the end of the fifth month all my cases showed a continued improvement and on auscultation I noted especially the absence of moist sounds, though on percussion dulness was still in evidence, but in some cases was not so extensive as it had been at the start. By the end of the sixth month every one had gained in weight to the extent of from three to seven pounds. Speaking generally, the younger the patient the greater was the gain in weight. The average increase in weight was 4·9 pounds, or somewhat less than one pound per month.

It is important to observe the sequence of events in the history of the patients' progress towards recovery as indicated in the foregoing statement. The first sign of improvement was in respect to the cough, always a troublesome symptom in these cases. In the majority marked improvement, so far as cough was concerned, showed itself by the end of the first month of treatment, while in every case before the end of the second month it was distinctly less harassing and troublesome. Whereas previously the patient had been kept awake from this cause, this disturbing element was entirely eliminated, and in consequence undisturbed *sleep was obtained.* With *lessening of the cough* came improvement in the expectoration, and that in two very definite directions. It became less in amount and also became less viscid and consequently easier of expulsion. In all my cases this was observed by the end of the third month, while in many a great improvement in the amount and nature of the expectoration was noted as early as the second month of treatment. No night-sweating was ever seen in any of the cases after the end of the fourth month and in some instances it was entirely absent before the end of the third month. Gain in weight was not, as a rule, observed until the patient had been under treatment for a considerable period, though two of the cases began to show an increase in weight about the end of the tenth week. At any rate, in six months' time all had gained in weight and put on flesh. In every case there was marked nutritional improvement and food was taken with greater relish than hitherto. Any gastric discomfort that had been present when the patients first came under treatment had entirely gone and altogether there was marked improvement in their general condition as well as in the pulmonary phenomena. Apart from gain in weight I cannot say that in my experience the younger the patient the earlier did improvement commence to show itself, nor, indeed, was the ultimate benefit greater in proportion to the youth of the patient. Age did not seem to count for much so far as treatment by ichthyol was concerned. More depended, I think, on the severity and extent of the pulmonary lesion and on the loss of nutrition that existed when the patient came under treatment. The graver the lesion and the greater the lack of nutrition the longer did ichthyol take to exert its beneficial influence.

---

[1] A paper read before the Therapeutical Society of London on Feb. 17th, 1903.

[2] A deposit of fossil fish found in the Tyrol Mountains.

Now I would not have any of you infer from my remarks that I claim to have cured any of my cases by administering ichthyol. Far from it, for no drug will, in my opinion, cure pulmonary tuberculosis. All that drugs can do in such cases is to arrest the disease, not to eradicate it. This I feel certain that ichthyol can and will do if properly administered. More must never be expected of it. I firmly believe that open-air treatment is the one and only hopeful mode of dealing with pulmonary tuberculosis, still I would have you bear in mind that at the present moment not all such cases can be sent straightway to a sanatorium. And this for two very cogent reasons: (1) because there are no immediate vacancies in many instances; and (2) because at the time the patients are probably not in a satisfactory condition to benefit by such treatment. With the first of these reasons we have nothing for the present to do. We certainly are in urgent need of more accommodation, but we can remedy the second defect. By placing such patients under a regimen of rest with, if practicable, daily massage and by administering ichthyol we may render them suitable for admission to a sanatorium.

But I now pass on to the consideration of two cases of bronchiectasis which I beneficially treated by means of ichthyol. In both cases the condition followed on chronic bronchitis. The most prominent symptoms were paroxysmal cough, with very abundant, fœtid expectoration. In one of the cases a history of slight hæmoptysis was obtained. When they came under treatment both patients showed considerable loss of flesh and had a remittent form of temperature. On percussion distinct dulness was obtained, with distant tubular breath sounds on auscultation, showing that the tubes were full of secretion; after a paroxysm of coughing and free expectoration the resonance became almost tympanitic, while the breathing was more markedly tubular and accompanied by coarse metallic râles. In cases of bronchiectasis I think one of the first essentials in the treatment is to obtain a regular expulsion of the fœtid material blocking up the tubes and poisoning the patient's blood. This I found ichthyol to accomplish in a very satisfactory manner. After a month's treatment the paroxysmal nature of the cough became less marked, while the percussion dulness grew less distinct. In three months the cough and expectoration were less troublesome, and the extremely fœtid character of the latter was scarcely noticeable. The patients were now gaining weight and were taking more nourishment. The temperature had also ceased to show its original remittent character. Dr. W. Ewart of St. George's Hospital has recorded[3] two interesting cases of bronchiectasis treated by postural exercises and ichthyol. The patients gained considerably in strength and in weight under this combined method of treatment. These, taken in connexion with the two cases which were under my care, go to prove the value of ichthyol in this very troublesome disease.

I should also like to refer to the use of ichthyol in the treatment of chronic pulmonary fibrosis as seen in stonemasons (i.e., stone-hewers). In such cases the chief symptoms are dyspnœa, cough with expectoration which is specially troublesome in the mornings, and gradual loss of nutrition. As a rule, so far as my experience goes, the tubercle bacillus sooner or later finds an entrance to the weakened pulmonary tissue, so that patients of this class seldom attain the age of 45 years. I have treated several of these cases for a time with ichthyol. In every case I found that the cough became less troublesome and the expectoration easier and less in amount. The general nutrition of the patients was improved and appetite, which was very poor in every case, gradually returned. Unfortunately, none of my cases admitted of careful and systematic treatment being carried out, as they could not be made to realise the importance of continuing the medicine. Still, from the experience I have had of these cases I feel bound to say that ichthyol is a most suitable remedy. Ichthyol has likewise proved itself of value in one or two cases of chronic bronchitis in which I have tried it, while in acute cases where the cough and expectoration were causing trouble ichthyol has stopped the paroxysms and caused the expectoration to become less difficult to expel. In pneumonia the cough is always more or less paroxysmal in character, while the expectoration at the height of the disease is very tenacious and viscid. Here, then, one would naturally find in ichthyol a suitable therapeutic agent, but it would be impossible, for various reasons, to administer a sufficient quantity even in capsule form to patients so acutely ill. Hence I have contented myself with studying its action during the resolution stage of this disease. I think I am right in stating that ichthyol is of value if administered after the temperature has been reduced, as it then seems to hasten resolution and to bring about a return of the lung to normal.

It may now be advantageous to say a few words regarding the dosage and mode of administration of ichthyol. Generally speaking, the amount given varied from eight to 20 grains four times per day. I always gave it in capsule form, each capsule containing four grains of ichthyol. As a rule, in every case I started with two capsules four times a day and then gradually increased the amount until five capsules were taken four times daily, this being the maximum limit. In other words, each patient got from 32 to 80 grains per day. This may seem a somewhat large amount, but it was tolerated in most cases when the drug was administered in the form of capsules. To some patients I found that the appearance of the capsule was somewhat repugnant, and after swallowing one they had considerable difficulty in taking a second, as the mere act of placing it in the mouth seemed reflexly to produce nausea. Apart from this I have never observed any nausea or sickness produced after ichthyol capsules were taken into the stomach, although some of the opponents of the drug state definitely that ichthyol is not tolerated by the stomach.

Dr. Heinrich Fraenkel in his treatment of pulmonary tuberculosis by means of ichthyol (of which a full account is published in the *American Journal of the Medical Sciences* for September, 1897) employed a solution containing equal parts of ichthyol and distilled water flavoured with oil of peppermint. He found that the odour and taste of this mixture caused nausea and even vomiting in sensitive individuals but never produced any true gastric irritation. If, however, gelatin capsules are prescribed, then, as already pointed out, no such phenomena are observed. Certainly, in my opinion, ichthyol does not in the slightest degree cause any irritation of the gastric mucous membrane, or if in a few anomalous cases it does produce slight inconvenience it is not nearly so great as that induced by creasote. I think anyone who has had any experience with both ichthyol and creasote will at once admit the truth of this assertion. I can quite readily understand trouble arising if ichthyol be given in solution and hence I would insist that in all cases the administration by means of capsules be selected. Sodium ichthyol may be substituted in this case. Firstly, as to the cause. The patient has aways lived near London and has never been abroad. The only possible source of infection seems to have been a pet dog which lives with the patient and which some few years ago was much troubled with tape-worm. Secondly, the course of the disease and the rupture of the cyst. That the true nature of the disease was not recognised before rupture of the cyst is hardly a matter for surprise, seeing that hydatid disease of the lung is rare and that there are several points in the medical history which obscured the clinical picture. The tuberculous disease of the ankle and the history of influenza and pleurisy seemed to furnish a sufficient explanation of the symptoms and physical signs. When did the cyst rupture? In most of the recorded instances of this occurrence there is a sudden gush of fluid through the air-tubes which threatens to suffocate or to drown the patient. No such escape of fluid occurred at any time in this case. Was the pleurisy diagnosed in November, 1901, really a collection of fluid which had escaped from the cyst into the pleural cavity? There are certain facts which lend support to such a supposition: (1) the absence of any fluid expelled from the mouth; (2) the fact, ascertained after the large pieces of membrane had been coughed up, that the patient had during a year or more occasionally coughed up small shreds of membrane suggesting rupture of the cyst some time ago; and (3) the feeling of something giving way within the chest whilst singing, followed by hæmoptysis. Both the hæmoptysis and the pleurisy may have been due to tuberculosis and the hydatid cyst in the lung may have had no connexion with these accidents. The condition of the apex of the right lung seemed to indicate the presence there of tuberculosis.

---

[3] THE LANCET, July 13th, 1901, p. 70.

The satisfactory result of the natural cure of the disease is also interesting. The physical signs before the patient left the hospital and on her subsequent visit to me indicated that a smooth-walled cavity containing air only was left and that this was contracting.

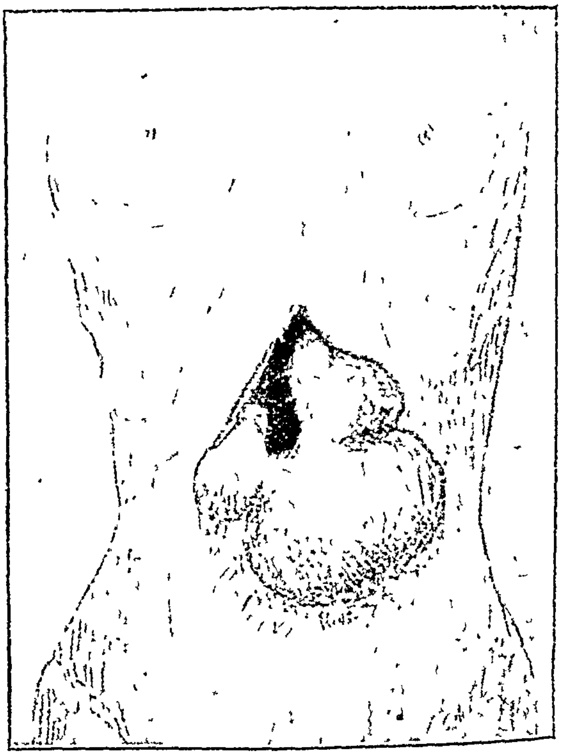
LEEDS GENERAL INFIRMARY.

A CASE OF TRIFID STOMACH.

(Under the care of Mr. B. G. A. MOYNIHAN.)

THE patient, a woman, aged 27 years, was sent to the Leeds General Infirmary by Mr. Arthur Knowles of Halifax. Nine years ago the patient, a thin, sallow-looking woman, began to suffer from pain after food and vomiting. The first "attack" came on quite suddenly when she was apparently in good health; the vomit was then copious and deeply tinged with blood. At repeated intervals since this there had been other "attacks" in all of which there had been vomiting, and on one or two occasions blood in small quantity had been ejected. The pain had been noticed after all foods, generally within an hour of a meal. All solids had been withheld for over 12 months on account of the pain which they caused. In her present condition she was constantly suffering from "indigestion." Even a drink of milk caused some pain, and every day or two there was an outbreak of severe vomiting. The fluid ejected was sour and at times very offensive. During the last four months there had been an increase in the symptoms and she had been losing weight rapidly. An examination of the abdomen was made; the stomach was inflated and subsequently washed out. On the following grounds a diagnosis of hour-glass stomach was made: 1. On washing out the stomach only 16 ounces were returned for every pint introduced. At the first washing five pints were used and four were returned. 2. An examination then revealed a succussion splash and "paradoxical dilatation." 3. On inflation there was a large increase in the subcostal tympany and the distension of the stomach in the epigastrium was observed much later than is the rule. 4. A loud, sizzling, forcing sound was heard over the left end of the stomach during this delayed distension of the epigastrium.

The abdomen was opened on Nov. 29th, 1902, and the stomach was exposed. An hour-glass stomach was at once recognised. There were two pouches with a constriction which just admitted the middle finger between them. The pyloric pouch was about equal in size to a small cocoanut; the pouch towards the cardia was of the size of a normal stomach. The stomach was then explored up towards the cardiac orifice, with the result that another constriction and another pouch were exposed. This constriction would only just admit the tip of the little finger. The pouch beyond it was rather bigger than the middle compartment of the stomach.



Semi diagrammatic representation of the trifid stomach.

The cardiac pouch, it may be noticed, is drawn smaller than it actually was, as most of it was not pulled outside the abdomen; the figure was drawn by Mr. W. O. Mayo who was administering the anæsthetic. There were thus three pouches in the stomach separated by two constrictions Both constrictions showed considerable induration and some puckering, the result of old ulceration. To remedy the defects the first pouch was united to the second by the operation of gastro gastrostomy, an opening being made that would admit three fingers easily; the second pouch was united to the jejunum by a posterior gastro-enterostomy; and the constriction between the second and third pouches was well dilated with the fingers. The patient's recovery was without incident. She left the infirmary on the twenty-third day after the operation and had been taking ordinary diet for a few days before this

Remarks by Mr. MOYNIHAN.—This case is the only one recorded in which a trifid stomach, the result of the contraction of old ulcers in the stomach, has been found Clinically the case was one of inveterate dyspepsia with recent increase in the severity of the symptoms and with recent rapid loss of weight. A diagnosis of hour glass stomach was made and at the beginning of the operation it was supposed that this diagnosis was confirmed. But I never begin any operation upon the stomach until I have exposed the whole viscus and until I have examined and handled the organ quite up to the cardiac orifice. It is only by acting upon such a resolve that one avoids the error of uniting the pyloric pouch of an hour glass stomach to the jejunum Hour-glass stomach is more common than is supposed. Including this case I have operated upon 16 patients affected with this disease; in 14 the constriction was due to chronic ulceration and in two to malignant disease. Mr. Knowles, who kindly sent the patient to me, writes to me that it "was owing to reading the previous recorded cases of yours in THE LANCET[1] that I was led to press the patient to come to you for operation. I felt sure she had an 'hour-glass stomach.'"

Reviews and Notices of Books.

The Diseases of Infancy and Childhood. By HENRY KOPLIK, M.D. London: Henry Kimpton. 1903. Pp. 675 Illustrated. Price 21*s*

THIS new text-book on the diseases of infancy and childhood will be read with considerable interest in this country where Dr. Henry Koplik's name is so well known in connexion with what is very generally regarded as the pathognomonic sign of measles Dr. Koplik, though, perhaps, most famous for his investigations in that branch of medicine which is concerned with specific fevers, has had a very wide experience in the general diseases of infancy and childhood, but heretofore he has not attempted to give others the benefit of his experience by writing a work which covers the whole ground of the medical diseases which affect young people. This book must be regarded in every sense as a complete and up-to-date treatise of the diseases of children. The space allocated to the various subjects is equably and judiciously apportioned and the chapters on the special infective diseases, which, owing to the author's special knowledge, might reasonably have received conspicuous attention, are neither unduly prominent nor disproportionately long. The mere fact that these chapters conform in all respects to the systematic design of the whole proves that Dr. Koplik's object in writing this book was to prepare a work which would be of general use to students and practitioners. The author's prefatory *apologia* for the publication of this recent addition to the already extensive library of books which deal with the same subject is therefore unnecessary, but when he adds that "the literature in the domain of pediatrics is largely inaccessible to those conversant with the English language alone" we may point out that there have recently been published at least four new editions of works which have brought the literature of the subject as satisfactorily up to date as does the volume under review. The value of Dr. Koplik's work in our opinion does not rest on its merits as a compilation but on its just claim as a document of personal observation and original and independent mind.

The first chapter, which describes the general examination of the patient, his development, and management, deals with questions in pediatrics which from a critical standpoint give better indications of an author's powers of observation and capacity for literary description than do the more or less routine accounts of the less definite diseases which are common to all periods of life. It is one thing to know a subject and another matter altogether to write about it intelligently and intelligibly, indeed many an able clinician has come signally to grief when he has laid down his stethoscope and has taken up his pen. The author describes in considerable detail the management of breast feeding and his account of the medical examination and selection of wet nurses will be found invaluable to medical men on whom this responsibility devolves. With regard to the general management of infants Dr. Koplik is clearly no advocate of the "hardening" system. His directions for the temperature at which nurseries should be kept and baths given would assuredly absolve him from the reproach of applying Spartan methods. It might perhaps be urged with some degree of justification that however necessary the measures which Dr. Koplik suggests might be in the case of genuinely delicate infants, if applied in the case of infants who are initially robust there might be some risk of the latter developing into individuals for whom this hot-house system might be urgently required. This, however, is a matter with regard to which mothers and nurses will continue to exercise their own judgment in spite of Dr. Koplik and in spite of other authorities who do not agree with him. With regard to the artificial feeding of infants it is almost refreshing to find that the author has no strong views in favour of any particular system, and although he recommends the application of the percentage method in the home modification of milk he is no advocate of the ultra refinements of which the method, according to other American authors, is apparently capable. Indeed, of so little importance does the percentage composition of different varieties of milk appear to be in the author's estimation that he makes the statement that asses' milk has a composition which is nearly identical with that of woman's.

Turning to the chapter which describes the specific infectious diseases it is impossible to avoid being impressed by the consummate and masterly skill with which this part of the work is handled; it would be difficult to find a better account of the efflorescences of the various rashes both on the skin and on the mucous membranes. Speaking of the rashes on mucous surfaces or enanthemata, as he calls them, which from time to time have been described as complicating the course of many of the specific fevers and which have been adduced as evidence against the specific character of the so called Koplik's spots, the author says: "None of these are constant or characteristic of rotheln, but all are found in other affections. The buccal mucous membrane, however, is absolutely free from eruption of any kind and in this fact we have a valuable diagnostic distinction between this disease (German measles) and measles." Interpolated between pages 148 and 149 is the now famous coloured plate of Koplik's spots in various stages of their efflorescence, and for purposes of differential diagnosis a similar illustration of aphthous stomatitis, an inflammatory condition of the mucous membrane sometimes confounded with the author's pathognomonic spots.

It is scarcely necessary to follow Dr. Koplik in his description of many of the general diseases which are incidental to childhood. In his arrangement and classification he has adhered to the best traditions of American authors. No attempt has been made to discuss controversial views or obscure pathological problems. Throughout this book we have a plain, unvarnished description of the symptoms and treatment of the ordinary complaints met with in practice But as we have already mentioned, it is for the individual manner in which Dr. Koplik regards the manifestation of disease in children and for the practical hints on treatment which his personal experience enables him to supply that this book will be chiefly valued.

Die Krankheiten der Warmen Lander: ein Handbuch fur Aerzte. (The Diseases of Warm Countries: a Handbook for Physicians) Von Dr B. SCHEUBE, früherem Professor an der Medizinschule in Kioto. Third revised edition. Jena: Gustav Fischer. 1903. Pp. v. + 789 Plates and Maps. Price, paper cover, 16 marks; bound, 18 marks.

THE third edition of this truly encyclopædic work on Tropical Medicine lies before us for review. That it has been appreciated by those for whom it is intended as a guide is shown by the rapidity with which successive editions have been published, the second appearing in 1900, and this, the third, in 1903. It is impossible in the space at our command to do full justice to the work in its entirety, but a glance at it suffices to show that this new edition is thoroughly up to date, and to those who are able to read German it will be found to constitute *par excellence* the standard text book on tropical diseases. There is only missing the description of one disease which we should have liked to be included—viz., heat stroke—whilst cholera is dismissed in but a few words. New sections on Filaria Volvulus, Rhabdonema Strongyloides, Leeches, Ground Itch, Veldt Sores, and Chappa are added. In the chapter on in this case. Firstly, as to the cause. The patient has aways lived near London and has never been abroad. The only possible source of infection seems to have been a pet dog which lives with the patient and which some few years ago was much troubled with tape-worm. Secondly, the course of the disease and the rupture of the cyst. That the true nature of the disease was not recognised before rupture of the cyst is hardly a matter for surprise, seeing that hydatid disease of the lung is rare and that there are several points in the medical history which obscured the clinical picture. The tuberculous disease of the ankle and the history of influenza and pleurisy seemed to furnish a sufficient explanation of the symptoms and physical signs. When did the cyst rupture? In most of the recorded instances of this occurrence there is a sudden gush of fluid through the air-tubes which threatens to suffocate or to drown the patient. No such escape of fluid occurred at any time in this case. Was the pleurisy diagnosed in November, 1901, really a collection of fluid which had escaped from the cyst into the pleural cavity? There are certain facts which lend support to such a supposition: (1) the absence of any fluid expelled from the mouth; (2) the fact, ascertained after the large pieces of membrane had been coughed up, that the patient had during a year or more occasionally coughed up small shreds of membrane suggesting rupture of the cyst some time ago; and (3) the feeling of something giving way within the chest whilst singing, followed by hæmoptysis. Both the hæmoptysis and the pleurisy may have been due to tuberculosis and the hydatid cyst in the lung may have had no connexion with these accidents. The condition of the apex of the right lung seemed to indicate the presence there of tuberculosis.

The satisfactory result of the natural cure of the disease is also interesting. The physical signs before the patient left the hospital and on her subsequent visit to me indicated that a smooth-walled cavity containing air only was left and that this was contracting.

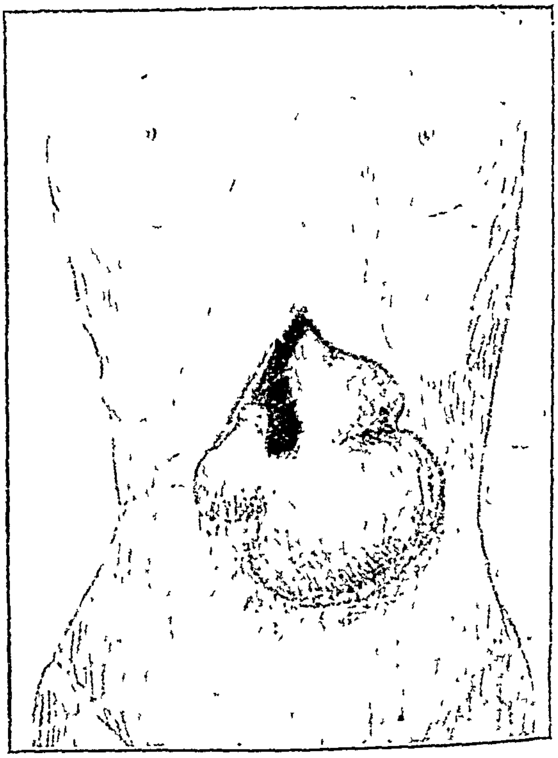
LEEDS GENERAL INFIRMARY.

A CASE OF TRIFID STOMACH.

(Under the care of Mr. B. G. A. MOYNIHAN.)

THE patient, a woman, aged 27 years, was sent to the Leeds General Infirmary by Mr. Arthur Knowles of Halifax. Nine years ago the patient, a thin, sallow-looking woman, began to suffer from pain after food and vomiting. The first "attack" came on quite suddenly when she was apparently in good health; the vomit was then copious and deeply tinged with blood. At repeated intervals since this there had been other "attacks" in all of which there had been vomiting, and on one or two occasions blood in small quantity had been ejected. The pain had been noticed after all foods, generally within an hour of a meal. All solids had been withheld for over 12 months on account of the pain which they caused. In her present condition she was constantly suffering from "indigestion." Even a drink of milk caused some pain, and every day or two there was an outbreak of severe vomiting. The fluid ejected was sour and at times very offensive. During the last four months there had been an increase in the symptoms and she had been losing weight rapidly. An examination of the abdomen was made; the stomach was inflated and subsequently washed out. On the following grounds a diagnosis of hour-glass stomach was made: 1. On washing out the stomach only 16 ounces were returned for every pint introduced. At the first washing five pints were used and four were returned. 2 An examination then revealed a succussion splash and "paradoxical dilatation." 3. On inflation there was a large increase in the subcostal tympany and the distension of the stomach in the epigastrium was observed much later than is the rule. 4. A loud, sizzling, forcing sound was heard over the left end of the stomach during this delayed distension of the epigastrium

The abdomen was opened on Nov. 29th, 1902, and the stomach was exposed. An hour-glass stomach was at once recognised. There were two pouches with a constriction which just admitted the middle finger between them. The pyloric pouch was about equal in size to a small cocoanut; the pouch towards the cardia was of the size of a normal stomach. The stomach was then explored up towards the cardiac orifice, with the result that another constriction and another pouch were exposed. This constriction would only just admit the tip of the little finger. The pouch beyond it was rather bigger than the middle compartment of the stomach.



Semi diagrammatic representation of the trifid stomach.

The cardiac pouch, it may be noticed, is drawn smaller than it actually was, as most of it was not pulled outside the abdomen; the figure was drawn by Mr. W. O. Mayo who was administering the anæsthetic. There were thus three pouches in the stomach separated by two constrictions Both constrictions showed considerable induration and some puckering, the result of old ulceration. To remedy the defects the first pouch was united to the second by the operation of gastro gastrostomy, an opening being made that would admit three fingers easily; the second pouch was united to the jejunum by a posterior gastro-enterostomy; and the constriction between the second and third pouches was well dilated with the fingers. The patient's recovery was without incident. She left the infirmary on the twenty-third day after the operation and had been taking ordinary diet for a few days before this

Remarks by Mr. MOYNIHAN.—This case is the only one recorded in which a trifid stomach, the result of the contraction of old ulcers in the stomach, has been found Clinically the case was one of inveterate dyspepsia with recent increase in the severity of the symptoms and with recent rapid loss of weight. A diagnosis of hour-glass stomach was made and at the beginning of the operation it was supposed that this diagnosis was confirmed. But I never begin any operation upon the stomach until I have exposed the whole viscus and until I have examined and handled the organ quite up to the cardiac orifice. It is only by acting upon such a resolve that one avoids the error of uniting the pyloric pouch of an hour-glass stomach to the jejunum Hour-glass stomach is more common than is supposed. Including this case I have operated upon 16 patients affected with this disease; in 14 the constriction was due to chronic ulceration and in two to malignant disease. Mr. Knowles, who kindly sent the patient to me, writes to me that it "was owing to reading the previous recorded cases of yours in THE LANCET[1] that I was led to press the patient to come to you for operation. I felt sure she had an 'hour-glass stomach.'"

[1] THE LANCET, April 27th, 1901, p. 1190.

American Armoury and Blue-book. Edited by JOHN MATTHEWS, Member of the Pennsylvania Historical Society. London: Published by the Author, 93, Chancery-lane, W.C. 1903. Pp. 558. Price £2 2s. net.—The idea of an American Armoury and Blue-book cannot fail to strike accurate-minded people as odd. American civilisation dates from the time when armoury and heraldry had begun to lose all their uses and much of their significance. Again, the men who have been in the forefront of the development of the Republic of the United States trace, and used to take some pride in tracing, their origins from those classes in the old world who did not happen to be bearers of arms. This, at any rate, was the case with Americans of British origin save in the colonies of Maryland and Virginia. The settlers under the Plymouth Company and the London Company, and the historic Pilgrim Fathers certainly did not comprise many people with the right to use arms, and we do not believe that the Dutch and Swedish settlers were a whit more aristocratic in their origin. By what process certain American families have arrived at thinking that they possess the arms figured in the American Armoury and Blue-book we cannot, therefore, guess, but some of the pictures are very funny and the letterpress is in keeping with them.

Where Shall I Send my Patient? Published by the Association of Medical Men Receiving Resident Patients. 1903. Pp. 279.—This is a guide for medical practitioners who want assistance with regard to finding convalescent homes, asylums, nursing institutions, or sanatoriums for their patients. The book is published by an association of medical men who receive resident patients, which was formed some three or four years ago with the object of providing homes for persons of good social position suffering from any kind of ailment requiring the constant supervision of a medical practitioner as well as the comforts of home life. 126 medical men give details of the facilities which they have for the reception of resident patients and of their abilities to look after them. The names of the medical men are not given but a number and a corresponding *non de plume* are published so that communications can be made through the honorary secretary of the association, whose address is Bodorgan Manor, Bournemouth. The idea of medical men coöperating in this way to make known to their medical colleagues their desire to receive a patient is a very sensible one, for it is particularly well known to us in this office that those who have facilities for receiving patients do not get quickly into touch with those who desire to find homes for patients.

The Charaka Club. Vol. I. New York; William Wood and Co. 1902. Pp. 97.—The Charaka Club is a small literary club organised some few years ago in New York by medical men interested in the artistic and historical aspects of medicine, the idea being to find recreation in meeting together to read and to discuss papers. The first volume of the proceedings of the club contains a selection of the papers that have been read and show the association to be inspired with something of the same blended spirit of seriousness and banter that used to distinguish the now defunct Rabelais Club. The essay entitled "The Evil spoken of Physicians," by Charles L. Dana, brings together some of the many bitter criticisms of our profession to which numerous great readers and thinkers have committed themselves since the compiler of the Chronicles recorded that Asa "sought not to the Lord, but to the physicians; and Asa slept with his fathers." Mr. Dana has brought together similar examples from Bacon, Pascal, Balzac, Molière, Arnold, Byron, Montaigne, and others, to show how numerous are the satirical comments of literary men upon physicians and surgeons. Another interesting paper is from the pen of the same author and describes at some length the Cult of Æsculapius. The story of the man who wished to hypnotise, by Mr. Joseph Collins, is witty if a little nasty.

MEDICINE AND THE LAW.

The Price of a Medical Practice.

IN the King's Bench Division an action was concluded on July 30th between Mr. E. K. Houchin, of Ilford, Essex, and Mr. John Marshall, of Stepney, in which Mr. Houchin sued Mr. Marshall for £987, balance of the purchase price of £2000 which the latter had agreed to pay for the plaintiff's practice in Stepney. The defendant admitted the agreement to purchase at the price named and that the balance was still unpaid, but pleaded in defence that he had been induced to purchase by the plaintiff's misrepresentations as to the value of the practice. These, he alleged, consisted principally in the statement that the average annual receipts of the practice exceeded £2000 a year and also that Stepney was a good and improving district. With regard to the condition of Stepney he contended that owing to the influx of poor alien immigrants the district was becoming worse instead of better, and he denied that the annual receipts of the practice were as stated to him. On behalf of the plaintiff it was contended that at the time when the statements were made they were perfectly true and that the alleged deterioration of Stepney as a locality for medical practice had not begun to take place in 1898 when the practice was sold. After the plaintiff and the defendant had given evidence it was announced by counsel that a settlement had been arrived at whereby Mr. Houchin made a substantial allowance to Mr. Marshall, and Mr. Marshall withdrew all imputations of fraudulent misrepresentation. The price paid for a medical practice is a matter with regard to which dispute may easily arise afterwards if every precaution is not taken by both parties at the time of purchase. The best way to avoid all difficulties is to rely solely upon carefully kept books in giving and in accepting information as to the value. The accounts of a medical practice are not complicated and do not require special skill to understand them if they are kept in a clear form. Opinions as to the future development of a district are opinions only, with regard to which a purchaser should seek such information as may enable him to test their accuracy for himself. It will be observed in the published reports of the case referred to that the judge and the jury both expressed their approval of the course adopted by the parties in arriving at an amicable settlement, clearly holding the view that the dispute was an unfortunate one, in which mistakes had been made involving no blame to either party.

An Action to recover Fees.

At the Liverpool Assizes, on July 29th, an action was heard in which Mr. J. D. Crawford of that city sought to recover a sum of £835 for medical attendance upon a deceased hotel-proprietor named Westmoreland and his wife. The executors of the deceased defended the action on the ground that the fees were excessive. Evidence was given that the deceased was a gentleman of considerable means, who left an estate of the value of £70,000 and who during his lifetime insisted upon very frequent medical attendance and advice. Medical practitioners other than the plaintiff gave evidence as to the reasonableness of the fees charged and the jury eventually found a verdict for the plaintiff for £699, for which judgment was accordingly entered. There can be no doubt that a medical practitioner is placed in a position of some difficulty by those patients who desire to see him more often than is strictly necessary in the interests of their health and who would at once transfer themselves to some other medical man should the first show any disinclination to humour a whim which they are ready and able to pay for. At the same time, an executor confronted with an account for medical attendance of more than £800 may quite reasonably examine it very carefully having regard to the responsibility of his position. On the other hand, in the course of the case referred to it was shown that Mr. Crawford had been paid without question £1030 for attendance upon Mrs. Westmoreland. The accounts in both instances are large and give rise to the question whether it is not more prudent to endeavour to obtain periodical payment than to risk having to bring an action for amounts so considerable. To prove attendances represented by £1000 to the satisfaction of a judge and a jury is in itself a matter which may not be easy.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT SWANSEA.

THE seventy-first annual meeting of the British Medical Association, which has now come to an end, was quite successful. The attendance of medical men was not so large as usual, partly, perhaps, on account of the remoteness of the place of meeting from any well-known seat of learning. This meeting was a jubilee visit to Swansea as the Association met there in 1853, a fact which had escaped our attention.

First impressions of Swansea were not lively, but the courtesy and kindness of everyone brightened those impressions. Those members of the Association who arrived at Swansea on July 27th approached the town through a thick murky canopy of smoke rendered especially disagreeable by heavy rain. Despite the elements, however, the streets were encumbered with a multitude assembled to do honour to their countryman, the Welsh Volunteer who had gained the King's Prize at Bisley and was returning to Swansea on that day. Visitors to Swansea had been warned not to expect anything beautiful in the place and the narrow monotonous streets in which no trace of architectural ambition appears looked their worst in the downpour.

Each member of the Association was presented by the Mayor and corporation of Swansea with a souvenir of the meeting in the form of an official album issued under the combined auspices of the corporations of Swansea and Aberavon, the Swansea Harbour Trust and the Chamber of Commerce. The book illustrates the furnaces, the docks, and the shipping of the place as well as some of the many charming spots in its neighbourhood. The publisher of the souvenir hopes that it may "form a factor in the material advancement and prosperity of Swansea" and we indorse the hope. Swansea cordially welcomed its medical visitors and they cannot fail to have carried away a kindly recollection of the town as well as a pleasant memory of the beauties of the environment.

In the annual report of the Association it is stated that the council has authorised the general secretary, when sending out the notices for the annual subscriptions, to intimate that he will also receive donations on behalf of the British Medical Benevolent Fund and the Royal Medical Benevolent College. It is gratifying to learn that these excellent charities have received as a result about £600 up to the end of March. It is quite easy to understand that the innovation may become a very useful one, seeing that members when writing their cheques for their annual subscriptions can without additional labour add their further donations on the same cheque.

The annual dinner of the British Medical Association at the meeting at Swansea was held on July 30th at the Albert Hall, Swansea, with the President of the Association, Dr. T. D. Griffiths, in the chair. Among those present were the Mayor of Swansea, Mr. Griffith Thomas, Mr. Andrew Clark, chairman of the council of the Association, Mr. D. A. Thomas, K.C., M.P., Dr. G. B. Ferguson, Surgeon-General G. J. H. Evatt, R.A.M.C., Sir A. Morris, Mr. H. E. Juler, Professor D. J. Hamilton, Sir J. Tyler, Mr. W. Whitehead, Dr. W. Collier, Dr. F. T. Roberts, Mr. A. W. Mayo Robson, Professor J. G. Adami, Professor H. Senator, Professor T. Glück, Mr. W. Arbuthnot Lane, Dr Dawson Williams, Dr. S. Woodcock, and Inspector-General H. C. Woods, R N. After the usual loyal toasts had been duly honoured Dr. Collier proposed, and Inspector-General Woods responded to, the toast of "The Navy, Army, and Reserve Forces." Mr. Thomas then proposed the toast of "The British Medical Association," which was acknowledged by Mr. Andrew Clark who took the opportunity of thanking the people of Swansea for the hospitable way in which they had entertained the members of the Association. Dr. Woodcock, in a witty and well-delivered speech, gave the toast of "The Swansea Corporation and Harbour Trust," which was replied to by the Mayor of Swansea. Dr. Roberts submitted the toast of "The President" and after this had been suitably replied to Mr. H. T. Thompson proposed the toast of "Our Guests and Friends from over the Seas." The hour being very late Professor Senator and Professor Adami briefly responded. In the course of the evening Dr. Arthur G. Haydon rendered two violin solos which met with an enthusiastic reception.

The council of the British Medical Association, at a meeting held on July 29th, resolved that a committee should be appointed to consider whether the general or the individual medical defence of its members shall be undertaken by the British Medical Association. If the committee report in favour of the Association undertaking medical defence of its members a scheme will be attached to the report according to which, in the opinion of the committee, the Association could safely and efficiently execute the work of medical defence. This is a very important question for the British Medical Association and one upon which a definite opinion should soon be arrived at, seeing how long proposals for the undertaking by the Association of defence work have been in the air.

The members of the Continental Anglo-American Medical Society lunched together at the Hôtel Métropole on July 30th in Swansea. The chairman was Dr. A. J. Freeman (San Remo). Mr. Edmund Owen gave the toast of "The Society" which was suitably acknowledged by Dr. F. M. Sandwith (Cairo). The health of the guests was submitted by Dr. Michael Foster, which was replied to by Dr. Frederick Roberts. Among those present besides the speakers named were Dr. Griffiths, Mr. Whitehead, Mr. Arbuthnot Lane, Sir Patrick Manson, Mr. F. Burghard, Professor Senator (Berlin), Professor Adami (Montreal), Dr. R. Ledermann (Berlin), Dr. Dawson Williams, Dr. L. N. Robinson (Paris), Dr. D. W. Samways (Mentone), Dr. H D. Rolleston, Dr. Ward Cousins, Dr. I. H. Cameron (Toronto), Dr. H. E. L. Canney (Assouan), and Mr. C. D. Marshall. The proceedings were not continued so long as usual because the Address in Surgery by Mr. Mayo Robson was delivered in the afternoon on the day on which this luncheon was held, but the function was nevertheless a complete success and those present looked forward to meeting again in Paris in October, 1904, at the International Congress on Tuberculosis.

THE SECTIONS.

MEDICINE.

THURSDAY, JULY 30TH.

Dr. H. D. ROLLESTON (London) introduced a discussion on

The Treatment of Gastric Ulcer.

Gastric ulcer had formed the subject of discussion before this section in 1900 when Dr. J. F. Payne opened the proceedings by a paper on the Problems of Gastric Ulcer which included the more restricted subject of its medical treatment chosen for consideration that day. In the following year Mr. H. G. Barling in the surgical section dealt fully with the treatment of gastric ulcer by gastro-jejunostomy. On the present occasion they were mainly concerned with the medical treatment of gastric ulcer. In the acute stage of an ordinary clinical case of gastric ulcer in a young woman, with localised tenderness, vomiting, and pain, the principle of absolute physiological rest, though universally accepted, was not so consistently carried out. While most medical men cut off all food by the mouth some allowed water, sips of water (hot or cold), or ice by the mouth to relieve thirst. Probably this depended in part on the erroneous belief that water was quietly absorbed by the mucous membrane of the stomach. As a matter of fact, water taken into the stomach was only absorbed in the intestine and had first to be expelled from the stomach by peristaltic action. In this way not only was healing delayed but a gastric ulcer might be so disturbed that severe hæmorrhage was induced. Dr. Rolleston had seen hæmatemesis set up when water was first allowed by the mouth five days after a previous hæmatemesis and when deep tenderness had disappeared. The better practice was to forbid any water by the mouth and to rely on rectal injections of from 10 to 20 ounces of water given slowly four or more times a day. The mouth should be kept as clean as possible by water or a mouth wash, such as Listerine. Reference was made to the occasional occurrence of parotitis as a complication in rectally fed patients. Mr. B. N. Tebbs had found from an analysis of the cases at St. George's Hospital that parotitis was more frequently a sequel of gastric ulcer than of other abdominal diseases, such as appendicitis, that the patients attacked were all on nutrient enemata, and that the routine use of antiseptic mouth washes did not protect against the incidence of parotitis. The latter point was of interest as it militated against the view that there was an ascending infection of Stensen's ducts from the mouth. The proteids of nutrient enemata should, of course, always be peptonised and the enemata should contain eggs and a sufficiency of salt, in addition to the ordinary constituents such as milk, beef-tea, and sugar, and might be given every four or six hours. The irritability of the rectum should be guarded against by washing out the bowel daily. It was, however, a question of considerable interest whether nutrient enemata were necessary during the period—usually from one to two weeks—in which no food was given by the mouth. It was somewhat surprising how well patients bore complete starvation when plenty of water was given by the bowel, and it had been epigrammatically said that nutrient enemata satisfied the minds rather than the bodies of the patients. As a result of careful chemical analyses of enemata, urine, and fæces in cases on exclusive rectal feeding Edsall and Miller[1] had concluded that in exceptional cases rectal feeding provided enough food to prevent tissue loss, but even then only maintained the patient in a condition of decided subnutrition. More efficient nutrient enemata could be given in a semi-solid form as advised by Leube, and Grünbaum[2] had advocated ox serum in rectal alimentation in combination with starch and glucose as a satisfactory method of supplying the necessary amount of caloric energy to the body and of minimising loss of weight. Attempts to bring about a cure and to prevent a relapse might be directed (1) to improving the general health and removing any underlying cause, such as chlorosis, syphilis, or oral sepsis; or (2) to the purely local treatment of the ulcer. In the mild cases commonly recognised as gastric ulcer in young women there was no doubt that as soon as gastric irritation had subsided iron was a most valuable remedy and should be taken to prevent a relapse in the same manner as in chlorosis. In the more chronic gastric ulcers usually seen in men after 30 years of age iodide of potassium should be tried, as a certain percentage of these ulcers were syphilitic in origin. Cautiously washing out the stomach with water or mild antiseptic solutions or running in a large amount of bismuth so as to get the local soothing effect of bismuth on the surface of the ulcer were curative measures sometimes employed. "Erosion" of the gastric mucous membrane had been treated by an intragastric spray of nitrate of silver (1 or 2 per cent).[3] In considering the medical treatment of gastric ulcer Dr. Rolleston said that the occurrence of vomiting indicated that absolute physiological rest should be given to the stomach and that nothing except drugs like opium, bismuth, and hydrocyanic acid should be given by the mouth. In some instances it appeared that the vomiting was reflex, due to the irritation of rectal injections, because it ceased on cautiously administering liquid food by the mouth and omitting rectal feeding. In a few cases the cause was probably oral sepsis and the swallowing of pus and micro-organisms, as shown by the fact that removal of bad teeth cured this symptom in two instances and improvement followed attention to the teeth in others. It was suggested that in some cases vomiting depended on the administration of common salt, which was given with eggs to increase absorption of the nutrient enemata. It was impossible and indeed unnecessary to enter fully into the treatment of hæmatemesis. Absolute rest, assisted by morphia hypodermically to quiet anxiety, was essential. Patients should not be allowed to suck ice. When hæmatemesis recurred or there were signs of continued though concealed hæmorrhage the administration of Ruspini's styptic or of adrenalin by the mouth for their purely local action on the bleeding spot and a rectal injection of a drachm of chloride of calcium, in order to increase the coagulability of the blood, might be given with advantage. Turning to the indications for surgical treatment, apart from perforation the only acute complication which required operative interference was repeated hæmorrhages which did not yield to medical treatment and were manifestly endangering life. Repeated hæmorrhages might be due (1) to an ordinary gastric ulcer with an exposed and ulcerated artery in its floor, or (2) to "exulceratio simplex" of M. Dieulafoy, or "pore-like erosions" of the gastric arterioles of Dr. J. Lindsay Steven. In chronic gastric ulcer operative interference was justified in the following circumstances: (1) When there was constant pain which was not relieved by medical measures and leading to a condition of chronic invalidism. This might be due to adhesions or might depend on the presence of a large gastric ulcer. 2. When there was intermittent or permanent pyloric obstruction. The first might be due to spasm set up by a chronic ulcer near the pylorus and was met by gastro-enterostomy; the second was due to cicatricial contraction. 3. When hæmatemesis recurred in spite of medical treatment.

Dr. T. D. GRIFFITHS (Swansea) remarked that mechanical and physiological rest of the stomach was the principal object of treatment and this was best carried out by rectal feeding. He emphasised the state of the mouth and tongue as a guide to the amount and kind of nutrient enemata. The bowel need not be washed out every day—every three or four days was sufficient. In early cases ten days of this treatment was sufficient and then the diet must be gradually increased as in the diet of infancy. From four to six ounces of predigested food might at first be given every four hours. Bodily rest was important—in most cases two or three weeks in bed were sufficient.

Dr. R. SAUNDBY (Birmingham) remarked that the diagnosis of this disease was incomplete. "Gastric ulcer" was a name applied to a group of symptoms which might or might not be attended by actual ulceration. The first principle in treatment was complete rest in bed. Physiological rest of the stomach was of equal importance. Sulphates of iron and magnesia mixed were the best drugs. When hæmatemesis was present feeding by the rectum must be adopted for a limited time. Symptoms must be relieved as they arose. Occasionally teaspoonful doses of olive oil relieved the pain, and morphia might be required. Death was very rare when the patient came under treatment before perforation had occurred. An ice-bag over the epigastrium was useful. He agreed with Dr. Rolleston that pyloric obstruction (spasm) and recurrent hæmatemesis were indications for operation, but constant pain as an indication must be considered in relation to the condition of the patient's nervous system.

Dr. W. J. TYSON (Folkestone) thought that every case of anæmia in young women should be regarded as a possible case of gastric ulcer. If this were done and such cases were kept under observation more completely much good would ensue.

Dr. H. W. KING (Chester) dwelt on the necessity of prolonging treatment long enough for the ulcer to heal. He did not agree with washing out the bowel every day. He never advised operation.

Dr. W. COLLIER (Oxford) had had to deal with about 180 cases of gastric ulcer, cases being so diagnosed in which hæmatemesis had occurred. He agreed with the principles of treatment mentioned by Dr. Rolleston and Dr. Saundby. Many anæmic patients complained of epigastric pain and they were too numerous to take into hospital, as suggested by a previous speaker. As to drugs, bismuth and iron were his favourite remedies.

eroding the whole thickness of the wall of the bowel and perforating the hepatic artery. It is probable that the manipulation necessitated by the delivery of the stomach for operation caused a fresh extension of the duodenal ulcer.

Mr. WHITE considered that the posterior operation caused unnecessary disturbance; he always employed anterior gastro-enterostomy, but he was careful to make the anastomosis not more than three-quarters of an inch from the gastro-colic omentum.

Mr. MITCHELL expressed his preference for posterior gastro-enterostomy and he considered it better that the jejunum should pass through the mesocolon than through the omentum. He wished to utter a protest against performing gastro-enterostomy indiscriminately for gastric ulcer. For all ordinary cases infolding the ulcer was quite sufficient to effect a cure; it acted probably by eliminating peristalsis.

Mr. KEETLEY thought that the supracolic route for gastro-enterostomy suggested by Mr. Hall had all the disadvantages of the anterior method and he considered that constipation with distension of the colon would give rise to obstruction by pressure on the jejunum.

Mr. T. H. OPENSHAW (London) was inclined to think the trans-omental operation the best method, it was so very much simpler. He agreed that gastro-jejunostomy was not necessary in all cases of gastric ulcer, for infolding or excision was quite sufficient.

Mr. HALL, in reply, said that in no case had the colon exerted obstructive pressure on the jejunum and therefore this objection was theoretical only.

OBSTETRICS AND GYNÆCOLOGY.

THURSDAY, JULY 30TH.

Professor MURDOCH CAMERON (Glasgow) read a paper on

The Diagnosis and Treatment of Uterine Fibroids.

He said that as regarded the association of sterility and fibroids he looked upon the latter as the cause rather than the result of sterility. In his own experience they were not more common in single than in married women. He drew attention to the fact observed by himself that fibroids in the fundus frequently caused a tumour having a "bullock's heart" shape. Some fibroids were soft and boggy, resembling an ovarian cyst. The submucous and interstitial forms gave rise to hæmorrhage. In the diagnosis he used the sound and when the latter was in the uterus and the tumour was moved the handle swayed from side to side. When causing no symptoms delay was advisable. If operation was required hysterectomy was the most satisfactory way of dealing with the case. Enucleation and oöphorectomy had been generally abandoned. The indications for operation were absolute, as pressure and hæmorrhage, and relative, as pain and discomfort giving rise to invalidism. In performing hysterectomy it was sometimes advisable to enucleate the tumour first so as to give room and in that case he would place an elastic ligature round the cervix during the enucleation.

Dr. HEYWOOD SMITH (London) thought that enucleation was sometimes very good treatment even when the tumour had a broad attachment, but they should follow the advice of Marion Sims and always complete the enucleation when once begun.

Dr. F. W. KIDD (Dublin) drew attention to the dangers of hæmorrhage and sepsis in cases of fibroid associated with parturition.

Dr. E. J. MACLEAN (Cardiff) had observed intermittent contractions in a fibroid tumour.

Dr. F. J. McCANN (London) spoke of the removal of fibroid tumours for æsthetic reasons.

The PRESIDENT, Professor W. STEPHENSON (Aberdeen), said that they were not justified in operating in cases of fibroid unless there was a distinct warning of danger to life. He had watched cases where women had carried fibroid tumours for 30 and 40 years with little inconvenience. He thought that the soft fibroid might diminish after the menopause but not the hard variety.

Dr. JAMES OLIVER (London) read a paper entitled

A Clinical Study of Internal Hæmorrhage in Association with Ectopic Pregnancy.

He said that in the early days of a tubal pregnancy if there was hæmorrhage the bleeding was not from the vessels of that portion of the wall of the tube which was in contact with the ovum but from those of the tubal wall on either side of the ovum. Hæmorrhage in uterine gestation was rare before the sixth week, but in tubal gestation it might occur at any time after the ovum had become detached and the blood found its way along the tube either to the uterus or the peritoneum. Tait laid stress on a previous history pointing to tubal disease and Parry in the same way mentioned the occurrence of previous sterility. This view was held till lately, but his own experience was opposed to this and he urged that too much importance should not be attached to it or a mistake in diagnosis would be made. Pain was the first symptom, the patient having either missed a period or not; in a small number of cases there was no preceding amenorrhœa. Sometimes the appearance of vaginal hæmorrhage was the first symptom. The passage of a decidual membrane was not as common as authors stated. Occasionally troubles of micturition and retention of urine were present and the latter could not always be put down to pressure but must be of reflex origin. Rupture occurred between the sixth and twelfth week and the hæmorrhage into the peritoneum might soon stop, but was apt to recur and to prove fatal. The hæmatoma had a peculiar doughy sensation difficult to describe but very characteristic. When there was hæmorrhage into the broad ligament there might be a large tumour as the ligament was distensible and permitted considerable extravasation; in these cases the uterus was fixed somewhat and some annular constriction of the rectum could be felt, especially if the left broad ligament was affected.

Mr. A. HORNE (Dublin) agreed with Tait's view as to previous sterility.

Dr. KIDD raised the question of pyrexia in intraperitoneal hæmorrhage even when no sign of suppuration was present.

Dr. O. E. PURSLOW (Birmingham) mentioned the liability there was to confuse uterine abortion with ruptured tubal gestation and thought that when the former was supposed to be present owing to the occurrence of abdominal pain and vaginal hæmorrhage the severity of the pain and particularly the occurrence of faintness should raise a suspicion that the case was one of tubal gestation.

Dr. T. WATTS EDEN (London) said that one after another former explanations of tubal gestation had had to be given up. Careful pathological and microscopical examination had failed to discover any signs of previous salpingitis and the tube outside the site of attachment of the ovum had been proved to be absolutely healthy. It had been shown that the ovum in the tube actually penetrated the muscular walls of the latter. He would ask Dr. Oliver why he thought that the hæmorrhage did not come from the site of attachment. A decidual formation in the uterus had been proved to be present in every case but it was not always discharged. He did not think that the vaginal hæmorrhage came from the tube but from the uterine decidua. There was sometimes much difficulty in diagnosing these cases from cases of uterine abortion. He thought that cases of extreme bleeding proving rapidly fatal were rare.

Dr. T. B. GRIMSDALE (Liverpool) had met with most cases in young newly married women and he thought that developmental peculiarities such as diverticula on the tubes were causes.

Dr. R. G. McKERRON (Aberdeen) agreed with Tait's view and thought that a history of previous sterility was important in the diagnosis.

Dr. J. A. C. KYNOCH (Dundee) believed that examination sometimes caused rupture of a gravid tube.

The PRESIDENT pointed out that the degree of collapse was not proportionate to the amount of hæmorrhage and that it was usually better to wait, carefully watching the pulse, which was the best guide. He attributed the pyrexia to the absorption of blood products.

Dr. OLIVER, in reply, thought that collapse in cases of pyosalpinx was due to leakage.

Dr. MACLEAN read a paper on

Two Successful Cases of Cæsarean Section for Contracted Pelvis in Dwarfs.

Conservative Cæsarean section was performed in each case and the patient was sterilised by removing an inch of each Fallopian tube. Both mothers and children recovered.

Dr. H. O. NICHOLSON (Edinburgh) read a paper entitled

Some Remarks on the Maternal Circulation in Pregnancy

which were enumerated as follows :—1. The hypertrophy of the heart which occurred during pregnancy was not always of a compensatory nature. 2. Signs of dilatation of the right heart in pregnancy (*a*) pulsation of the jugular veins, (*b*) systolic murmurs over the præcordia, (*c*) increase in cardiac dulness to the right, and (*d*) inconstancy of the arterial pulse in different positions of the body 3 A possible explanation of the cardiac hypertrophy and dilatation in pregnancy—contraction of the arterial and arteriole systems 4 The influences which regulated the arterial calibre (*a*) the vaso motor centre, and (*b*) the internal secretions of the suprarenal and thyroid glands 5 The different types of circulatory phenomena observed during pregnancy might possibly be related to disturbances of the normal influence exerted on the vascular system by these internal secretions (*a*) two opposite types of circulation occurring in pregnant women, and (*b*) some features of each type 6 Pre eclamptic symptoms and arterial constriction—value of thyroid extract and other vaso dilators in controlling these symptoms.

STATE MEDICINE

WEDNESDAY, JULY 29TH

Dr J C McVAIL (Glasgow), the President of the section, opened a discussion on

The Vaccination Acts and the Prevention of Small pox

He said that as the Government had determined to introduce during the present session no fresh legislation on the question of vaccination they were still in the position of discussing not what the law was but what it ought to be The value of vaccination as a preventive of small pox was not for them a matter of opinion, it was a matter of knowledge There was no reason whatever to suppose that small pox could be stamped out of Britain without vaccination and revaccination The work of persuading people to accept protection should always be done with discretion and advice should not be pushed too far If after reasonable persuasion a "contact" would not accept vaccination his subsequent attack by small pox might have quite an admirable effect in bringing about the vaccinal protection of a whole village The prevalence of small pox in the provinces emphasised the importance of obtaining by Act of Parliament special powers for meeting special difficulties When small pox threatened the Local Government Board should have special powers to issue epidemic regulations such as they now possessed with regard to threatened outbreaks of cholera or plague In these regulations the prevention of the spread of small pox by tramps should be dealt with for the opportunities which vagrants had of carrying the disease from village to village and from town to town rendered them a most serious danger to the nation The compulsory vaccination or re vaccination of "contacts," though at first this course might appear desirable, he did not advocate, but proposed that all tramps within a defined area should be examined and if necessary vaccinated, while in certain instances 'contacts' should be detained for a specified period Ample powers should be given not only for the inspection of premises where tramps or navvies resort but also for the examination of the inmates There was practically unanimity of opinion regarding the necessity for a thorough and proper performance of the vaccinal operation, and it was also conceded that calf lymph should either be provided by the Government or if produced by private makers these should work under Government supervision or certificate The authorities to administer the Vaccination Acts should be, in his opinion, the county councils or sanitary authorities exercising powers over extended areas, but whatever authorities had charge of the Acts they should be relieved of all responsibility as to the prosecution of defaulters In every case there should be a public prosecutor directly under the Local Government Board instead of as at present a vaccination officer appointed by the guardians but requiring to act independently of them The vaccination officer's relation to the matter should consist in handing to the public prosecutor, who would no doubt be a local lawyer, periodical lists of defaulters who had neither submitted to vaccination nor obtained an exemption certificate It would be for the central authority, in consultation with their local prosecutor, to determine what cases should be taken to court and what cases should be passed by The primary purpose of the Vaccination Acts was not to punish anti vaccinationists but to promote vaccination, and punishment of anti vaccinationists was wise only in so far as it promoted vaccination By means of consultation between the local prosecutor and the Local Government Board prosecutions might often be avoided where their effect would be not to advance but to hinder vaccination

Mr T W H GARSTANG (Altrincham) said that the question as to whether every medical practitioner should be paid by the State or whether the present system should be continued was only a matter of detail which might very well be decided when a new Vaccination Bill was introduced He proposed the following motion —

> Medicine Section of the British
> i the council the importance of
> Association for bringing before
> the country by means of local
> necessity for further legislation
> -evaccination

The motion was seconded by Mr HERBERT JONES (Hereford)

Dr A E MOLE (Gower) thought it was most unreasonable that a public vaccinator should be sent to vaccinate 'contacts" who might be the patients of another medical man *Lymph should be supplied to all private practitioners who* should be paid a fee for all successful vaccinations.

Mr GARRETT HORDER (Cardiff) considered that the administration of the Vaccination Acts should be in the hands of the sanitary authority and hoped that the new education authority would have school children periodically inspected with a view to discovering those who were unprotected by vaccination and if the Government were not prepared at present to make revaccination compulsory the education authority might urge children to be revaccinated before leaving school He had long been of opinion that public vaccinators should be officials who devoted their whole time to the work of vaccinating

Mr J M MACKENZIE (Kirkby in Ashfield) doubted the wisdom of whole time appointments, he did not altogether approve of a medical officer of health being debarred from private practice *He did not think that the private practitioner* had any grievance against the public vaccinator who offered vaccination to children outside his own practice, for these children were practically the children of the State

Mr W JONES MORRIS (Portmadoc) protested against a statement which had been made that public vaccinators were kept in office by doles

Mr J RANKIN (Kilmarnock) urged systematic and not spasmodic vaccination. The operation should be performed during infancy, then at seven years of age, and again at the age of 14 years

Dr JOSEPH GROVES (Isle of Wight) said that if all practitioners were paid by the State for vaccinating there would be a difficulty in connexion with inspection The Local Government Board would have to increase its staff of inspectors very considerably if inspection were properly carried out

Mr EBENEZER DAVIES (Swansea) urged revaccination before the wage earning age maintaining that a workman preferred the remoteness of small pox to the immediate certainty of incapacity for a few days He said that during the recent outbreak of small pox in Swansea there were 14 000 persons revaccinated and not one contracted the disease Before the epidemic the vaccination returns showed that 10 per cent. of the children born in the town were unaccounted for, but since the epidemic all but 4 per cent were accounted for

Dr J BRASSEY BRIERLEY (Old Trafford) disapproved of whole time public vaccinators and considered that those who had brought discredit on vaccination were those practitioners who only made one mark

Dr J M MORRIS (Neath) advocated an annual inspection of *the inmates of common lodging houses for the purpose of* securing the revaccination of tramps who, he maintained, were the chief cause of the spread of small pox

Dr C R. DRYSDALE (London) said that they were all convinced that vaccination prevented small pox but not for life They ought, therefore, to take a firm stand and say that children should be revaccinated at the age of 12 years. He proposed the following motion which was seconded by Mr H. H TIDSWELL (Swansea) —

> i in cities of the
> list in Germany
> of on account of
> e under a law of
> on under a law of
> s performed with
> animal vaccine, this meeting is of opinion that all children in the United Kingdom should be vaccinated in infancy and revaccinated at the age of ten or 12 years and that animal vaccine alone should be

causing pes equinus. The left foot was sometimes cold and its skin was tense, shiny, and livid, sometimes dark purple or blackish, and at others scarcely different in appearance from that of the other foot. Heat or cold applied caused pain but a dependent position did not. Scars of ulcers and effects of the gangrene were to be seen on both feet. The right foot, except for these and some pigmentation and purpuric spots, seemed healthy. The plantar reflexes were absent on each side; the knee-jerk was increased on the left side but diminished on the right side. The left leg was much wasted but its muscles showed no degenerative electrical reactions. Pulsation could be felt in the tibial arteries in both extremities. There were no signs of disease in the thoracic or abdominal organs. There was no albumin or sugar in the urine. The pupils were equal and reacted naturally. No abnormalities of sensation were observed. Mr. Michels performed Chopart's amputation of the left foot; the arteries were not found to be blocked and the wound healed well. When the patient left England, two years and seven months after his first symptoms, the wasting of muscles was much less and he had no pain. Microscopical sections of the skin of the foot, which had been cyanosed for a long time, showed great thickening of the walls of the arterioles. Sections of the internal plantar artery and dorsal artery of the foot showed decided thickening of the middle coat but no endarteritis obliterans or thrombosis. Sections of the extensor brevis digitorum muscle showed characteristic ischæmic myositis with atrophy of the muscle fibres, interstitial fibrosis, and thickened arterioles. The nerves showed nothing abnormal. The bones of the foot were atrophic. A study of this case seemed to favour the view that a variety of obliterative arteritis might commence in the arterioles of the extremities. And although the peripheral nerves microscopically examined appeared to be normal the presence of a nervous element might explain its occurrence and would connect some cases of obliterative arteritis with Raynaud's disease and erythromelalgia as well as with trophic disorders of the extremities in tabes dorsalis and syringomyelia.

Professor **THOMAS OLIVER** (Newcastle-on-Tyne) was next called upon to open a discussion on

Miners' Diseases.

He commenced by defining miners' phthisis as a disease exhibiting signs and symptoms in the lungs of a more or less chronic character and occurring in miners whose lungs after death were deeply pigmented and somewhat solidified. It was generally regarded as the result of breathing a dust-laden atmosphere—a variety, therefore, of pneumoconiosis—anthracosis for coal-miners, silicosis for quarrymen, and chalicosis for gold-miners being appropriate names in the different cases. The ventilation of coal mines and the operation of the mining laws had made miners' phthisis much less common of late years. The disease was first described in 1703 by Ramazzini. In 1860 Peacock identified microscopically and chemically the dust in the lungs of a patient with that in the atmosphere he had been working in, and Zenker showed the same in a girl, the red colour of whose lungs was due to oxide of iron particles which occurred in the air of her place of work where red paint was made. These and other facts showed pneumoconiosis to be a dust disease due to occupation. In this discussion Professor Oliver proposed to consider whether continued breathing of dust could cause phthisis. The operation of such complicating factors as alcohol, syphilis, previous illnesses, and tuberculous infection in the home and elsewhere made human pathology insufficient to solve the problem. The greater part of the dust they breathed never reached the lungs at all but was caught on the mucous membrane of the mouth, throat, and nose, or if it reached the trachea and bronchi was caught by the mucus and removed by ciliary action or by coughing. The lungs, however, of dwellers in towns did become pigmented, yet without symptoms. Causes must occur in order to make the condition pathological. These might be intrinsic, such as defect in the epithelium of the respiratory passages, or extrinsic, such as a heavily dust-laden atmosphere. Naso-laryngeal and ordinary naso-oral breathing, if the mucosa of the upper air-passages was healthy, was shown to be a barrier to the entrance of dust into the lungs by the readiness with which pneumoconiosis developed after tracheotomy. The nature of the dust, its quantity, and the depth of the inspiratory process largely determined its effect on the epithelium of the lungs. Secondary infection might be prepared for by irritation diminishing resistance. In spite of this the lung was able to remove dust if the inhalation of it was interrupted. Control animal experiments supported this observation and it explained the relief obtained by men who after working in a dusty atmosphere were able to have a long break in their occupation. Turning to the pathology of miners' phthisis Professor Oliver related the manner in which the black particles of dust were carried by the wandering cells of the finer bronchi, which were distinctly phagocytic and mobile, through the branched plasma spaces into the lymphatic canals under the pleura and thence by way of perivascular or peribronchial vessels to the bronchial glands. Experiments of feeding amœbæ with coal dust showed that they absorbed without any apparent harm not only fine dust particles but a few quite large particles within 24 hours of its being given to them. In ordinary circumstances the lining epithelium of the bronchi efficiently barred the entrance of dust to their walls. Fibrosis soon followed the entrance of dust to the alveolar walls. But since anthracosis might be present without symptoms and since this fibrosis appeared to result from irritation, some other factor seemed necessary to cause it. Professor George Murray had failed to find micro-organisms in coal. It had been suggested that it was the presence of particles of stone in the dust besides coal. Drawings of sections of the lung of a Transvaal gold-miner who died from phthisis showed excessive fibrosis with signs of catarrh in the alveoli and the presence of large round phagocytic cells laden with pigment. The dust conveyed by these cells exercised an irritant action and led to fibrosis, and subsequent degeneration of the cells which englobed them liberated the dust particles which then lay free in the fibrous tissue. Professor Oliver considered the fibrosis of miners' phthisis to be usually non-tuberculous and possibly a natural attempt to get rid of the dust. Tubercles with giant cells might, however, be found, but to discover tubercle bacilli was difficult. Their presence probably indicated a secondary infection rather than primary. Cavities in anthracotic lung might conceivably result from necrosis following obliteration of vessels by fibrosis or be bronchiectatic, or, as in some cases, might indicate a tuberculous origin. Excepting nitrogen peroxide, a gas which was given off by the higher explosives and which caused acute pulmonary congestion, the inhalation of gases could not be regarded as having any causal connexion with pneumoconiosis. Referring to the experimental production of anthracosis, Claisse and Joué's work went to show that with soot or charcoal a considerable degree of pigmentation of the lung took place without disturbance of breathing or circulation, but secondary changes due to bronchitis, broncho-pneumonia, the dust itself, or tubercle led to dyspnœa. The hardness of the dust particles was important. Dealing with the relation of anthracosis to tubercle Professor Oliver showed that finding tuberculous lesions in the lung on post-mortem examination did not prove the disease to have been due to tuberculosis, nor, on the other hand, was it always easy to detect the tubercle bacillus when it was present. In the case of the gold-miners' lung clinical and pathological evidence supported the statement that the disease throughout was non-tuberculous. In this connexion the high mortality and bad ventilation in constructing the St. Gothard tunnel were mentioned by Professor Oliver in comparison with the much lower mortality and rarity of phthisis in the Simplon now being made, in which ventilation was very good and stone-dust was avoided, although the workmen's lamps made the air very smoky. Although in the case of the liver the injection of tubercle bacilli into the blood going to it could produce marked fibrosis Professor Oliver did not think that they played any part in the fibrosis of anthracosis but that in some way not yet fully understood the macrophages which conveyed the dust particles into the lung were responsible for its occurrence. The much easier development of anthracosis experimentally after division of the vagi was mentioned but not discussed.

In the discussion which followed Professor **J. G. ADAMI** (Montreal) agreed with Professor Oliver on the whole as to the pathology but questioned whether the phagocytes played a direct part in causing fibrosis, stating that a large deposit of foreign bodies is sufficient to cause fibrosis without the intervention of phagocytes—as when round a bullet, for instance. He agreed that the occurrence of tuberculosis should be regarded as a secondary condition implanted on weakened lungs and he deprecated the use of the term "coal-miners' phthisis."

The PRESIDENT, who next spoke, also thought "coal-miners' phthisis" a bad term. He saw in coal-miners the condition of "black spit," which he believed to be an aseptic slough of lung tissue much more than a fibrotic condition, while among the men in the freestone quarries intense fibrosis was characteristic of the silicosis from which they suffered. He regarded the strong basement membrane in the bronchial tubes as an efficient agent in protecting them from deposits of dust. The macrophages which Professor Oliver referred to he regarded as really alveolar cells and doubted if they conveyed particles of dust. Finally, he stated that never yet had he seen a case among coalminers of tuberculosis but he had seen many amongst stonemasons.

Professor OLIVER, in reply, pointed out that the softness of the Midlothian coal probably accounted for the absence of fibrosis, while pigmentation was extreme. In reference to the phagocytic view he had based his opinion on the appearances in animals experimented on in which within a few hours of insufflation of dust these large cells were seen to increase in numbers in the alveoli and were seen full of particles in the vessels and spaces. Professor Oliver illustrated his remarks on these cells with some beautiful drawings showing large angular pieces of dust in the alveoli, while in the walls and spaces were seen the large cells containing minute finely divided black granules.

THURSDAY, JULY 30TH.

The business which occupied the attention of the section was a discussion on

Splenic Anæmia.

Dr. H. D. ROLLESTON, who opened the discussion, began by pointing out how vaguely the term "splenic anæmia" had been used in clinical medicine to denote the association of anæmia with enlargement of the spleen when the cause of the enlargement was not due to any well recognised cause. In consequence, the examination of the blood sometimes gave discordant results, since secondary anæmias, such as those due to tubercle or cirrhosis of the liver, might be regarded as splenic anæmia and their true cause found on post-mortem examination. Although, therefore, diagnosis might be a matter of very great difficulty and mistakes were, and often would be, made this did not disprove the existence of splenic anæmia as a disease. Dr. Rolleston then enumerated the clinical characters of the disease in question: (1) splenic enlargement which could not be correlated with any known cause; (2) absence of enlargement of the lymphatic glands; (3) anæmia of a type midway between secondary anæmia and chlorosis; (4) leucopenia or at most no increase in the number of white blood corpuscles; (5) an extremely prolonged course lasting years; and (6) a tendency to periodic hæmorrhages, especially from the gastro-intestinal tract. He next proceeded to discuss the existence of a pathological condition of which these were the symptoms. Cases, he said, did occur which showed after death no lesion but that of a chronic change in the spleen, but more was required of clinical pathology for the diagnosis of chronic splenic anæmia from secondary anæmias, and to know the significance of reaction to the tuberculin test would be of value. The structural changes in the blood, the spleen, the bone marrow, and the lymph glands were next discussed individually, as well as the relation of chronic splenic anæmia to Banti's disease, and finally the pathogeny was dealt with. A diminution of erythrocytes less than in pernicious anæmia and a low hæmoglobin value occurred. The experience of Osler was quoted who gave the average red corpuscles count as 3,425,000 and the lowest 2,187,000 and the hæmoglobin average as 47 per cent. In severe cases poikilocytosis and nucleated red cells, especially normoblasts, were found. The leucocyte count in adults was important. Except for complications causing leucocytosis secondarily such a condition was absent; in fact, leucopenia occurred. The average number in Osler's cases was 4520 per cubic millimetre. More differential counts were needed but there were generally an increase in mononuclear cells and a diminution of polymorphonuclear cells, and according to Da Costa 5 or 6 per cent. of mast cells were sometimes present. The same observer stated that the blood presented no definite picture by which splenic anæmia could be diagnosed from some other conditions and Ewing found similar changes in the blood in lymphadenoma and in gumma of the spleen. In reference to the spleen Dr. Rolleston remarked its enlargement especially in chronic cases; up to 12½ pounds in one case of 13 years' duration and an average of 58 ounces in 13 other cases. Localised thickenings of the capsule occurred and perisplenitis was common. Fibrosis of the organ was seen on section. The microscopic appearances differed but might conceivably have been the result of various stages in the same process. Fibrosis of the organ, atrophy of the lymphoid elements, and fibrosis of the corpuscles of Malpighi with absence of pigmentation or other evidence of hæmolysis were features common to all. The three types of the disease which he then described were: (1) cases which only showed fibrosis of the organ with atrophy and fibrosis of the Malpighian bodies; (2) cases like the first but with endothelial proliferation of the lining of the blood sinuses of the pulp in addition; and (3) rare cases in which endothelial proliferation had so increased that the large venous blood sinuses of the pulp were filled with large cells of from 13 to 16 μ. These cells had clear protoplasm and some had more than one nucleus, while others showed active karyokinesis. Endothelioma or carcinoma had been names applied to this condition which thus simulated them. Gaucher in 1882 described it as primary carcinoma of the spleen and Picou and Ramond in 1896 did the same and suggested that it arose from fœtal inclusions of pancreatic cells, which Peremeschko had previously described. The proliferation of the endothelium spread from the sinuses to the vessels which showed endarteritis, a process which favoured thrombosis and cut off the blood-supply. Endophlebitis of the splenic vein thus resulted and Banti considered that the terminal cirrhosis of the liver was induced by an extension of this process to the portal vein. Extension of the endothelial proliferation from the splenic blood sinuses to the lymphatic vessels and a similar change in the lymphatic glands in the hilum of the spleen had been described. Dr. Rolleston next discussed the relation of these morbid appearances to each other. He thought it unlikely that the proliferated endothelial cells eventually formed fibrous tissue, as Bovaird suggested, or that the endothelial cells passed away leaving only fibrous tissue, for with regard to the latter view the extreme endothelial proliferation occurred in the cases of long duration and with regard to the former view it seemed more probable that a chronic intoxication caused endothelial proliferation simultaneously with fibrosis. The cases with marked endothelial proliferation might have perhaps been uncomplicated cases due to a specific cause, if there were one, while those with fibrosis might have resulted from a mixed infection. The view, however, which Dr. Rolleston himself favoured was that the two conditions were quite distinct. He then suggested some questions which arose as to how far the morbid changes in the spleen were pathognomonic. He knew of no other disease in which endothelial proliferation occurred, but then it only occurred in a few cases of splenic anæmia. The nature of the fibrosis, its distribution in the spleen, and its relation to that produced in rabbits by injection of meta-toluyen-diamine or other substances, or to the result of chronic bacterial poisoning or other chronic inflammatory conditions, should be considered. Recorded observations on the marrow in long bones again gave discordant results. Sometimes no change, and at others extension of the red marrow into the shaft had been found. Of the condition of the lymphatic glands very little was known beyond the anatomical fact that they were not enlarged. Besides this must be remembered Picou and Ramond's observation of the condition of the glands in the hilum of the spleen. In discussing the relation of splenic anæmia to Banti's disease Dr. Rolleston pointed out how other diseases existed of splenic anæmia associated with cirrhosis of the liver which with Banti's disease seemed to form a series: (1) chronic splenic anæmia; (2) chronic splenic enlargement and jaundice but no cirrhosis; (3) Banti's disease—splenic anæmia terminating with cirrhosis of the liver, jaundice, and ascites; and (4) splenomegalic biliary cirrhosis in which the symptoms were the same as in Banti's disease but in which, according to that observer, the condition was one of chronic congestion, while in the disease bearing his name it was one of fibrosis, atrophy of the Malpighian bodies, and diminution of the veins. Chauffard insisted that biliary cirrhosis might result from poisons formed in the spleen having reached the liver by the splenic vein and that the other large tributary of the portal vein tapped another source of poisons—the intestinal canal. If a chronic intestinal intoxication or infection caused the disease removal of the spleen would not cure it as it sometimes did unless the cause at first derived from the intestine had become confined to the spleen subsequently. Recent experiments by Charlton of repeated [illegible] a non-virulent strain of the bacillus coli peritoneum or veins of rabbits were of importance in that he obtained extreme diminution of erythrocytes, a corresponding fall in hæmoglobin with the presence of poikilocytes and nucleated red cells but absence of leucocytosis. In some cases of chronic splenic anæmia microscopic examination of the liver showed slight but arrested fibrosis—a condition almost the reverse of Banti's disease. In dealing with the subject of the pathogeny of splenic anæmia Dr. Rolleston mentioned that sometimes splenectomy might cure the disease and if done for rupture of the organ in healthy people did not induce the disease, which therefore could not arise from suppression of its function. A theory which assumed that hæmolysis occurred in the spleen by virtue of an enzyme manufactured by the endothelial cells, while it accounted for the blood changes since these cells were so increased, failed to explain the cause of their increase, and the blood in splenic anæmia appeared the very opposite of that in pernicious anæmia, where great blood destruction is believed to occur in the portal area. Since removal of the spleen seemed sometimes to have cured the disease it was possible that the anæmia depended on splenomegaly and that they were not both concomitant effects of a chronic toxic or infective condition of the blood, but that this gave rise to endothelial proliferation and later to fibrosis or to atrophy of the Malpighian bodies and to the blood changes. There was no experimental evidence to show that an animal could produce autolysins for its own tissues or that the lymph glands showed such chronic changes as were produced in guinea-pigs by injection of splenotoxin; hence it was unlikely that the spleen produced cytotoxins which destroyed the red and white cells. No micro-organism could be correlated with the splenic change. Until it was settled whether or no the disease was an intoxication or an infection any reply to whether splenic anæmia was an established pathological entity would have to be suspended or given in the negative.

Dr. TREVOR, who was next called upon to speak, described in detail the morbid appearances of the spleen, mentioning its enlargement and increased weight, the localised thickenings of its capsule by perisplenitis or lamellar fibromata, and on section the homogeneous look owing to loss of the speckles caused by the Malpighian bodies. Endarteritis and endophlebitis of the vessels occurred and atheromatous and calcareous patches were met with. An exceptionally remarkable instance of this was shown by Dr. Trevor in the pathological museum; calcification of the splenic vessels was extreme and two aneurysms occurred on the splenic artery. The histological changes met with in splenic anæmia might be summed up as: (1) atrophy of the Malpighian bodies brought about either by an over-growth of the connective tissue ensheathing the central artery or by an encroachment of fibrous tissue from the periphery; (2) thickening of the capsule and the trabeculæ, the walls of the vessels and of the fine fibrous reticulum forming the walls of the spaces of the splenic pulp; and (3) proliferation of the endothelium lining the splenic vessels and blood spaces of the pulp. The proliferated endothelium appeared in the form of large cells with clear protoplasm and peripherally situated nuclei, and in some instances they completely filled the blood space. Occasionally giant cells were present. Dr. Trevor then briefly gave the opinions of various authorities on the pathology of the condition and related an account of each of the three cases from which he had obtained the specimens which he was exhibiting. The patients were all males, aged respectively 23, 53, and 35 years, and the duration in two cases 12 years and nine months respectively. A table of 11 cases which had been drawn up to show whether the period of the disease had any bearing on the sequence of the symptoms gave a negative answer to the question. Dr. Trevor next turned to the consideration of whether the appearances of the spleen described as distinctive of splenic anæmia were really to be taken so, and concluded that judging only from the spleen this would be impossible, yet with the knowledge of changes elsewhere it might complete the picture of a case of splenic anæmia. Finally, in reference to lymphadenoma he thought that the appearances seen in that disease did not resemble those of splenic anæmia.

Professor SENATOR (Berlin) next in his remarks expressed the opinion that splenic anæmia could not be separated from other diseases of hæmopoietic organs. The spleen in this disease exhibited hyperplasia first of the pulp and later of the connective tissue. There was hyperæmia and the cells were very phagocytic, were large and rounded and with large vesicular nuclei. Many cells were probably of hypoblastic origin from the endothelial cells. Professor Senator almost always had found other abdominal glands enlarged. Myelocytes occurred in the blood. The bone marrow showed embryonic appearances (the normoblasts and giant cells were decreased) and collections of lymphoid cells occurred as grey spots. The liver showed alterations of three kinds: (1) small collections of round cells like lymphocytes—metastatic lymphomata; (2) collections of large endothelial cells like those in the bone-marrow and spleen; and (3) cirrhosis, sclerosis of the intima of the splenic or portal vein often due to syphilis, especially inherited syphilis. In some cases cirrhosis was secondary and a consequence of splenic changes. Swelling of the spleen was independent of the liver and was at first due to congestion. The existence of large endothelial cells coming from the spleen pointed to the liver changes being secondary to the splenic. Ascites did not always occur and might occur earlier than in Banti's disease. It might be due to the blocking of the lymphatics, to the swelling of the spleen, or to the congestion of the organs. A specific organism for the disease had been often sought for but never found. Swelling of the spleen might also be due to the condition of the blood, as in malaria, Barlow's disease, &c. The injurious substances coming from the intestine and the constant swelling of the abdominal lymph glands pointed to this. The injurious substances need not always be the same and so different hæmopoietic organs might be affected. Lymphadenoma resulted from the entrance of a noxious agent by way of the upper part of the alimentary tract. Finally splenic anæmia should be united under the term pseudo-leukæmia with diseases of other hæmopoietic organs.

Dr. J. MICHELL CLARKE (Clifton, Bristol) next spoke, mentioning a case in which the erythrocytes numbered 1,900,000 and the hæmoglobin index was 22 per cent. The white cells were 3500 and gave a differential count of polymorphonuclears, 56 per cent.; small lymphocytes and transitional cells, 25·3 per cent.; large mononuclears, 11 per cent.; and eosinophiles, 0·3 per cent. In another case the differential count was the same, and in a third case of only six months' duration the erythrocytes were 3,430,000, hæmoglobin 42 per cent., leucocytes 8000, and the differential count gave normal proportions. He thought that the frequency of severe hæmorrhages must affect the blood count. As to the occurrence of ascites, when it was present it was not always caused by cirrhosis of the liver. Heart weakness with chronic congestion of the liver and spleen and impoverished condition of the blood, possibly by the presence of toxins, might account for it. He thought also that a chain of dark-red, enlarged lymph glands running from the hilum of the spleen along the upper border of the pancreas was of pathological importance. Another important point was the absence of fatty degeneration in any of the organs, thus contrasting with pernicious anæmia and chlorosis. In reference to the cause Dr. Michell Clarke strongly favoured the view that the disease was the effect of a toxin reaching the spleen by the blood stream. In conclusion he referred to some cases of anæmia in which the blood showed the appearance of secondary anæmia, but no cause could be assigned for the large spleen.

Dr. W. EWART (London) related the clinical history of one of his cases of splenic anæmia from which was obtained the remarkable specimen of calcification and aneurysm of the splenic artery.

Dr. F. M. SANDWITH (Cairo) made a few remarks on the occurrence of the disease in Egypt stating that it was not very uncommon in children, so that here alcoholism as a cause could be excluded. Jaundice rarely occurred. In one case of a man, aged 22 years, 30 pints of fluid were drawn off from the abdomen. The liver in this case was not enlarged.

The PRESIDENT, summing up his ideas of what had been stated, remarked that in this disease the spleen was subject to certain conditions of fibrosis and sometimes giant cells were produced, that the liver showed a tendency to cirrhosis, that in the blood the erythrocytes were diminished without there being leucocytosis, and that he thought these might be epiphenomena while the true pathology was to be found from research upon the intestine, the source of a toxin causing hæmolysis and changes in the liver and spleen, and he suggested for research an investigation of the flora of the intestine.

After the discussion the members attending the section adjourned to the lantern room for a demonstration by Dr. CLARKE on Degenerative Changes in the Spinal Cord in cases of Diphtheritic and Alcoholic Poisoning affecting the Anterior Horn Cells and their Fibres.

OPHTHALMOLOGY.

WEDNESDAY, JULY 29TH.

Mr. H. E. **JULER** (London), the President, opened the proceedings with a short address directing attention to the subjects proposed for discussion and then called upon Mr. A. **STANFORD MORTON** (London) to open a discussion on

The Operative Treatment of Conical Cornea.

Mr. Morton said that the operative treatment of this condition was beset with difficulty and that an examination of the results obtained under varying methods would be useful. He excluded from the inquiry cases capable of improvement by the use of glasses. The object was to flatten the cornea, which could be done either by the cautery, with or without perforation of the cornea, or by the excision of the apex of the cone. He had tried each method and he handed round a record of 13 cases which he had treated, giving the visual acuity of each case with and without glasses, both before and after operation, and also indicating the degree of permanence of the improvement obtained. In the average there was a high degree of improved vision. Excision he had tried first; he preferred a vertical wound, which was more easily protected by the lids. He had used the cautery to burn concentric zones, as favoured by Sir Anderson Critchett, and had in cases perforated the cornea. There were risks associated with each procedure: in excision there was danger from synechiæ, anterior and posterior, from rise in tension, and from hypopyon; in perforation by the cautery the same risks attended. Doubtless these risks were diminished in cauterisation without perforation but they were not abolished. As regards scars, excision left the cleanest cornea. He concluded by reading a letter from Sir Anderson Critchett who agreed that the excision of the cone presented special advantages in some cases, but thought that the best average good result was obtained by the cautery without perforation; he emphasised the necessity of making the central burn as deep as possible.

Mr. J. **TATHAM THOMPSON** (Cardiff) said that of late he had used the cautery almost solely, burning deeply just short of perforation. The results from this mode were most gratifying. He provided for the scar of the burn by making a small optical iridectomy beforehand.

Dr. **KARL GROSSMANN** (Liverpool) said that he had given up excision for the cautery. He intended to try the effects of projecting upon the cornea a minute stream of very hot air.

Mr. **RICHARD WILLIAMS** (Liverpool)—the original introducer of the use of the cautery for conical cornea—said that he preferred to use the cautery and to perforate the cornea. He had never seen hypopyon, synechiæ, or other ill-effects follow; his results were uniformly good. He thought that a deep pit of the cornea short of perforation tended to increase the scar, even to leave a dimple. His rule was, in the case of one bad eye and one improved with glasses, not to operate at all.

Mr. R. W. **DOYNE** (Oxford) and the **PRESIDENT** both said that they had formerly practised excision but now always used the cautery.

Mr. **MORTON**, in reply, said that he did not like sutures in the cornea in any case, much less when, as in this disease, the cornea was peculiarly thin. As regards iridectomy he thought the procedure would be a disadvantage in most cases, since he found the vision markedly diminished on the use of a mydriatic, probably by reason of the loss of the stenopæic fissure existing between the corneal scar and the edge of the pupil. He had performed iridectomy on occasions but only because of special circumstances. On the question of perforation or non-perforation of the cornea in the use of the cautery, he felt that to aim at cauterising just short of perforation was to attempt the impossible, for burning deeply might cause sudden perforation. The size of the ellipse excised by the cutting method should be about two millimetres.

Major **HENRY SMITH**, I.M.S. (Jallundhar, Punjab), read a paper on

Extraction of Cataract in its Capsule.

He referred to the discussion on this subject at the meeting of the Association in 1901 and to a statement by Mr. Richardson Cross that "the ideal extraction was of the whole lenticular body in its capsule." In India this operation had been practised since the early "seventies" by several officers of the Indian Medical Service and the utility of the operation had been such that he hoped its use would become more general. In the first four months of this year Major Smith had extracted 1023 lenses in their capsules. Of these 99·42 per cent. had first-class results in visual acuity; 0·19 per cent. were second-class; and only 0·39 failures. The dangers of the operation were in the possible escape of vitreous, which occurred in 6 6 per cent.; and premature bursting of the capsule, which occurred in 8 per cent.; but more serious was the leaving behind of portions of the ruptured capsule, which occurred in 4 per cent. of the cases. Such accidents did not necessarily spoil the final result as was indicated by the very high percentage of first-class cases. His method was by an ordinary sclero-corneal incision, with or without iridectomy, as the particular cases indicated (most were done without iridectomy), then steady and long-continued coaxing pressure above and below the corneal incision, above with a spoon, below with a blunt hook; by this means the lens ligament was ruptured and the lens was delivered entire. The visual results were such that with a + 8 D. lens 60 per cent. of the cases could pass the military dot test at from 40 to 50 feet, whilst 20 per cent. passed at 20 feet.

Mr. N. **BISHOP HARMAN** (London) said that his only experience of extraction of cataract in the capsule was in a case of hypermaturity with increased tension produced by the irritation of the lens. When the tension was relieved by the making of the initial corneal incision the lens rose up bodily from its resting-place and escaped on to the cheek where it burst, leaving only a little fluid, some capsule, and an amber-like bead, the relic of the nucleus. The case did well, but the occurrence was not one that was pleasing.

Dr. W. A. **BRAILEY** (London) said that in his opinion the force required to rupture the lens ligament was so great that it would be difficult to avoid loss of vitreous.

The **PRESIDENT** said that he had seen the operation performed by one of his colleagues at the Westminster Ophthalmic Hospital and there was in most cases a loss of vitreous which was not desirable.

Major **SMITH**, in reply, said that the pressure required was not a serious objection, for it was gentle and prolonged and hæmorrhage from the tearing of the ciliary processes was very rare. He thought that the difference in the reparative processes in the British and Indian races was not of much account, for if at home there were cases of bad alcoholic subjects there were in India very bad cases of malarial subjects which were, he thought, much the worse to operate on.

Dr. A **DARIER** (Paris) read a paper on

The Treatment of Serious Syphilitic Diseases of the Eye.

In grave syphilitic lesions which had proved rebellious to ordinary treatment he recommended that before hope was abandoned there should be instituted an intensive and systematic course of mercury. He employed the intravenous injection of cyanide of mercury in progressively increasing doses, commencing with one or two milligrammes of the salt and rising to as much as five milligrammes daily until the reaction limit was reached, as indicated by the onset of colic. After from 12 to 15 such injections the effect could be much increased by the concurrent subconjunctival injection of the salt. By the adoption of three or four cycles of such treatment with intervening periods of rest and the use of pilocarpine he had obtained most satisfactory results in peculiarly obstinate forms of syphilis of the eye. The treatment should be repeated two or three times in the year.

Mr. **SYDNEY STEPHENSON** (London) said that he had recently made an extensive trial of Dr. Darier's method in some hitherto hopeless cases; in one such there had been relief of the conditions in three months. He thought that the treatment promised much for the future.

Dr. **DARIER** also read a paper on

The Subconjunctival Injection of Koch's Tuberculin (T.R.) in a Case of Interstitial Keratitis of Tuberculous Nature.

The case was one of complete degeneration of the cornea; the disease had lasted two years and the sclerosis of the cornea was such that it gave a porcelain-like appearance to the structure. All other means had failed; warmth, fomentations, atropine, mercurials, and even jequirity produced no reaction after the first instillation. He then instilled a strong solution of tuberculin into the cul-de-sac without producing any effect. The subconjunctival injection of the same fluid was, however, most intense in its action; in fact, he feared for a while for the integrity of the eye, but ultimately the eye regained a visual power amounting to $\frac{1}{18}$.

THURSDAY, JULY 30TH.

Mr. **EDWARD NETTLESHIP** (London) opened a discussion on

Ocular Changes in Relation to Renal Disease.

He said that although much was already known about the eye changes in renal disease information was still needed both from ophthalmologists and physicians upon several points, and the following heads were suggested as furnishing matter suitable for further investigation. 1. Did albuminuric retinitis ever occur in primary acute nephritis other than the kidney affection of pregnancy? 2. Cases of retinitis from lardaceous disease of the kidneys and from nephritis due to inflammation of the bladder, ureter, or pelvis of the kidney should be recorded. 3. The retinitis of pregnancy. Observation of such cases was desired (1) in which the kidneys were known to be diseased before the first pregnancy and (2) in which there was positive evidence that they were sound. All cases of pregnancy retinitis should be examined for signs of established chronic nephritis. The propriety of inducing premature labour may depend partly upon the diagnosis in this respect. 4. Age and sex. There was a great need for careful records of cases of renal retinitis in young subjects. 5. He recognised two chief factors in the production of renal retinitis—the state of the blood and the state of the retinal blood-vessels. He narrated cases in which a condition of visible disease in the retinal arteries had been noted without evidence of kidney disease; in some such cases there had followed, sooner or later, unequivocal signs of chronic nephritis. 6. It has been recently asserted that the characters of the retinitis in different cases justified inferences as to the kind of nephritis (chronic interstitial or chronic parenchymatous) from which the patient suffered. Attention was called to the importance of watching the course of the retinal disease from beginning to end and of distinguishing between the two kinds of white opacities. 7. Retinitis occasionally occurred in cases exhibiting both glycosuria and albuminuria; they had to determine which produced the eye changes. Retinitis in diabetic persons, whether their urine contained albumin or not, occurred later in life than albuminuric retinitis, but the relative liability of the sexes was about the same as in the ordinary albuminuric retinitis (excluding pregnancy cases). 8. Other points that needed elucidation were: the influence of scarlet fever and inherited syphilis in producing the chronic renal disease leading to retinitis; the occurrence of renal retinitis in only one eye; cases in which more than one attack of retinitis had been seen and watched through, with special reference to the changes left by the first attack and to the effect of retinal atrophy upon the characters of a second attack; the cause of the frequent peripheral pigmentation left by renal retinitis; the cause of the night blindness occasionally met with in renal retinitis; the nature and ophthalmoscopic appearances of the choroiditis said to occur in some cases of albuminuria; and the nature of the white, opaque thickening of the coats of the arteries and the veins seen after some cases and of the appearances resembling retinitis pigmentosa after others.

Dr. George Carpenter (London) said that observation had led him to the opinion that the most frequent cause of retinal changes found in children was congenital syphilis.

Mr. Henry Power (London) narrated two cases which well illustrated the variability of the prognosis to be attached to the symptoms according to the condition of the subject. In the first case a man, aged 35 years, there was sudden impairment of vision, spots appeared about the fovea which seemed to indicate albuminuric retinitis, yet neither he nor the physician could find albumin in the urine. Three weeks later the eye changes had increased and the vision diminished; then there were abundant changes in the urine and death followed rapidly. In the other case, during a pregnancy there were marked eye changes. He thought then the prognosis was grave, but the patient had recovered completely.

Mr. Gustavus Hartridge (London) was inclined to think that the prognosis might follow the radical distinctions of the causes of the conditions. In one case the cause was of a toxic nature—changes in the blood; of this order were the cases occurring in pregnancy. The second order of cases arose from changes in the blood-vessels; these were much more serious cases and death was much more likely to follow at an early date. He was inclined to think that pigmentation frequently followed the retinitis of pregnancy and that this pigmentation indicated the high-water mark of the œdema.

Mr. A. Q Silcock (London) said he had failed to find retinal changes in cases of surgical kidney even when there was prolonged suppression of urine from obstruction by calculi or otherwise. On the other hand, he found such changes were common in the nephritis of cardio-vascular origin.

Dr. R. A. Reeve (Toronto) narrated the case of a young man who had come under his care and in whom there was sudden visual failure with typical retinal changes. Death ensued in one month.

Mr. Doyne (Oxford) asked what importance was attached to the supposed compression of veins by arteries. He did not think the lumen of the vein was seriously diminished by such overlying—at any rate, not so as to cause distal accumulation of the blood—seeing that the arteries were at the same time diminished in calibre by degenerative changes. The fact that the early symptoms of the disease were much more frequently seen in women than in men he accounted for by the greater number of women attending hospitals, men refraining from attending until the latest date possible.

The President emphasised the uncertainty attending the prognosis to be attached to such retinitis. Doubtless the prognosis attending albuminuric retinitis was serious but it was not wise to predict early death for all cases, for in some such instances the patients condemned were yet alive.

Mr. Nettleship replied.

Dr. K. Grossmann (Liverpool) read a paper on

The Mechanism of Accommodation.

He demonstrated by lantern slides the observations made as to the influence of the instillation of strong solutions of eserine in the case of a young man whose eyes presented the conditions of aniridia and fine anterior and posterior polar opacities, the bulk of the lens substance being quite clear. The eyes were hypermetropic to + 7D.; there was some corneal astigmatism. By careful measurement he was able to demonstrate changes of shape and position of the lens on using eserine; the diameter was diminished by two millimetres and the thickness at the centre by 1·4 millimetres; there was an increase of spherical aberration and the lens moved upwards and inwards. He considered that these observations supported the theory of accommodation propounded by Tscherning.

Mr. Bishop Harman said that he did not under-estimate the interest of the case, but he thought that it was a little dangerous to utilise such observations as these in support of a theory relating to such an intricate phenomenon occurring in healthy well-developed eyes; the eyes on which Dr. Grossmann had made his observations were distinctly abnormal; there were aniridia and cataracts and the change of position of the lenses on the instillation of the eserine seemed to him to indicate that there was also some deficiency of the suspensory ligament.

Mr. Silcock and Mr. Nettleship also asked questions concerning the case.

Mr. W. A. Hancock (London) and Mr. W. T. Lister (London) communicated a paper on

Some Rare Epithelial Tumours of the Conjunctiva.

In all they had observed four cases, two in young subjects and two in adults; the conditions were of varying duration, one being as long continued as ten years while another was first seen after three months' growth. Their position differed in each case. The affected portions had been excised and the tissue had been examined histologically. Mr. Hancock and Mr. Lister showed lantern slides of the sections. The thickenings were seen to be due to a simple hypertrophy of the epithelial layer. There was no evidence that they were in the nature of dermoids, they certainly were not malignant, and there was no suggestion of a xerosis formation. In one case only there was a history of injury preceding the formation. They noted that similar epithelial plaques had been described by French authors.

Mr. Stephenson read a paper on

Interstitial Keratitis in Acquired Syphilis.

He recognised two varieties of corneal affections in syphilis: (1) general parenchymatous keratitis; and (2) the "keratitis punctata" due to a specific infiltration of the interstitial substance—a localised gummatous condition. He narrated several cases of the conditions described by others and one that had recently come under his observation. The consensus of observation was that the affection was most commonly unilateral and that it readily responded to mercurial treatment. He thought that a fair number of cases of interstitial keratitis in young children might be more correctly ascribed to a mild acquired taint rather than to the congenital. As regards the position of the manifestation with relation to the general course of the disease he thought that it was distinctly tertiary, an indication which was supported by the common association of choroiditis. It had been said that vascularisation of the cornea was not so common in the acquired form as in the congenital; this was not wholly his experience.

Mr. C. Devereux Marshall (London) mentioned a case which had come under his notice where the choroid was seriously and first affected, the keratitis being much later.

Mr. Stephenson replied.

Mr. Doyne read a paper on the

Treatment of Atrophic Retinæ with Retinal Extract.

His first idea in attempting this form of treatment was the possibility of supplying the diseased retina with a supply of food likely to be useful to it; the results of his experimental use of the extract on cases was such that he was now inclined to think that the retina contained some active principle which had an influence upon its nutrition. He insisted on the necessity of using the fresh glycerine extract; extracts of stale eyes he had found to be useless. There was some difficulty at present in getting the eyes, especially as the tentative dose was from six to ten fresh eyes daily. He confessed his willingness to ignore any effects produced in cases of hysterical amblyopia, for such cases were notoriously easy to treat by any suggestive and impressive procedure. He relied upon the results obtained in retinitis pigmentosa (five cases), in every one of which real and distinct improvement was found, and in toxic amblyopia (four cases) in which he considered the improvement in visual acuity to be more speedy than that following ordinary treatment.

Mr. Stephenson said that he had made use of this treatment in one case of tobacco amblyopia with what he considered to be important results. He suggested the use of the extract by subconjunctival injection.

Mr. Nettleship wished to point out that sufficient emphasis had not been laid on the condition of the tobacco amblyopia which had been treated. Acute cases did normally recover quickly. He did not wish to appear hypercritical towards a possibly valuable mode of treatment, but in one of the cases quoted by Mr. Doyne he had not been able to convince himself that there had been an appreciable improvement.

Dr. F. W. Edridge-Green (London) said that after his investigation into the visual purple of the eye he had tried to prepare an extract of this substance which might be used medicinally; he had not succeeded. He thought that such a mode of medication as attempted by Mr. Doyne was both possible and physiological.

Dr. Darier said that he had attempted several modes of such treatment some years ago after the publication of Brown-Séquard's work. He had injected various ocular extracts subconjunctivally and he had obtained in some cases some improvements, but such possible improvements were quite transitory. Further, he had had similar transitory benefits following the subconjunctival injection of various iron salts. He confessed that he was surprised to hear of Mr. Doyne's successful results by ingestion by the mouth when direct local applications had failed.

Mr. Doyne replied. He said he was hopeful that the matter would be taken up and given a fair and exhaustive trial.

Tests for Colour Blindness.

Dr. Edridge-Green brought forward the following motion:—

> That the council be requested to give effect to the resolution passed by this section last year that a colour-vision committee be appointed to recommend an efficient test for colour blindness.

He said that in the experience of many the present official tests were inefficient; very many varieties of colour blindness escaped detection, whilst some perfectly normal folk were rejected by it. Several such cases had been recently published.

Mr. W. M. Beaumont (Bath) thought that the matter ought to be taken up by some efficient body so that the two tests—that of Holmgren as now used and the test put forward by Dr. Edridge-Green—might be fairly considered.

The President put the motion to the meeting and it was agreed to without dissent.

DISEASES OF CHILDREN.

Wednesday, July 29th.

The Pathology and Treatment of Chorea.

Mr. Arbuthnot Lane, the President, was in the chair.

Dr. D. B. Lees (London) opened this discussion, remarking in the first place on the inadequacy and incorrectness of the term "chorea," inadequate because the disease was not merely muscular and incorrect because the lesion did not manifest itself in purely rhythmic movements and certainly not in dancing displays. The muscles most markedly under voluntary control were those most decidedly affected. Hence the muscles of the face, the tongue, and the hands were more perceptibly involved than those of the trunk and lower limbs, while those of respiration might suffer and that of the heart escape. He therefore thought that chorea must be considered as a disorder of the brain and particularly of the motor area. But there would appear to be in some instances an implication of the purely mental functions, as evidenced by the emotional and other similar manifestations shown by the young sufferers. There seemed, possibly, to be an overflowing of the impulses to the speech centre to the motor centres, with the result that the child when asked a question would answer as it were by primary choreic movements of the hands and facial muscles. The motor centres were not only irritable but were also actually weak—in fact, true paresis was by no means infrequently present. In some instances speech might be actually lost from possible involvement of the laryngeal muscles and not recovered for many months. It was interesting to note that even a kindly question might induce an emotional storm, with a downpour of tears, but no verbal reply. Marked anæsthesia was but seldom a symptom of chorea. An actual affection of the spinal cord or of the peripheral nerves might possibly be in evidence, as witnessed by occasional increase in the knee-jerks, in flying neuralgic pains, in the rare optic neuritis, and the accompanying constipation. In chorea what was most prominent seemed to be a disorder of the whole cerebral centres and in some cases possibly of the entire nervous system. But this lesion had the peculiarity of not being destructive—in fact, it was usually completely recovered from. Was it not, then, of the nature of a toxæmia, though probably not a toxæmia pure and simple, owing to its very localised effect in many cases? The relationship, to his mind, of chorea to rheumatism became more and more evident the closer the phenomena of the two diseases were examined. He believed that much could be learned from a closer attention to statistics bearing on the after-history of children who not having had rheumatism previously to an attack of chorea were afterwards smitten with it and he alluded to some significant figures in this relation obtained by Dr. F. E. Batten. Much importance must be attached to the recent valuable researches of Dr. F. J. Poynton and Dr. A. Paine into the bacteriology of rheumatism and their bearing upon chorea. It must now be acknowledged that there was a distinctive evidence of a morbid blood-state in chorea. There was the same also in rheumatism and any of the manifestations of rheumatism might therefore occur along with chorea and, in fact, choreic movements might in reality be the first symptom of rheumatism and rheumatism should be suspected in every case. The exhibition of anti-rheumatic modes of treatment had an undoubted success in acute chorea, provided they were vigorously pushed. Large and frequent doses of salicylates were required. The supposed depressant action on the heart muscle was in reality due to acute rheumatic dilatation of that organ and the drug was in no way responsible for it. Chronic cases were naturally not so markedly influenced by salicylates and probably because the motor centres might remain unduly excitable long after the action of the micro-organisms had ceased. Yet even in these cases salicylates were of decided service, as also were other remedies, such as arsenic, antipyrin, and ergot. He was certain that every case of chorea should be kept in bed in its early stages and treated exactly as for acute rheumatism, when distinct improvement would soon manifest itself.

Dr. H. Ashby (Manchester) felt that Dr. Lees had unduly exaggerated the connexion of rheumatism with chorea and therefore he was perhaps too sanguine in the results of treatment by those drugs which were of such great service in true rheumatism.

Dr. Theodore Fisher (Clifton) was convinced of the not uncommon association of cardiac manifestations in the course of chorea and brought forward statistics which bore out his contention.

Dr. W. Ewart (London) also drew attention to distinct cardiac lesions occurring in choreic patients and mentioned specific instances of the same.

Dr. G. J. Crawford Thomson (London) questioned the advisability and utility of large doses of salicylates.

Dr. F. J. POYNTON (London) drew attention to what he believed was an important factor in the production of the choreic movements—namely, the affection of the pia mater, induced probably by the toxin present in these cases.

Dr. E. CAUTLEY (London) thought that the almost, if not entire, absence of hyperpyrexia in choreic cases was an argument against the rheumatic origin of the disease.

Dr. M. O'SULLIVAN (Dublin) read a paper on the Complications, Course, and Treatment of Chorea, based on the careful observation of 54 cases. In many there was a distinct traumatic history. In no case were choreic movements the result of imitation. Mitral regurgitation was not infrequent as a cardiac complication. He had been much struck by the large and sometimes flabby condition of the patients' tongues. Cardiac mischief was most frequent in recurrent cases. With regard to the condition of the superficial and the deep reflexes in cases of chorea, in some both were exaggerated, in others the deep reflexes were well marked while the superficial were absent, and in others the superficial were well pronounced while the deep were wanting, and still more rarely both sets might be absent. The treatment adopted had been chiefly prolonged rest of mind and body, while arsenic was used as the best drug. Salicylate of sodium was given as a preliminary in cases with rheumatic symptoms.

Dr. G. CARPENTER (London) and Dr. J. R. LOGAN (Liverpool) took part in the further discussion and Dr. LEES briefly replied, stating that he was so convinced from his actual experience of the value of salicylates in the treatment of chorea that he regarded them in the light of a specific for the disease.

The Relation of the Thymus Gland to Marasmus.

Professor RUHRAH (Baltimore, U.S.A.) said that there were two forms of atrophy of the thymus gland, primary and secondary. The organ had an undoubted relationship to nutrition. In a large number of fatal cases of marasmus in infants he had never failed to find what appeared to be primary atrophy of the thymus.—Dr. POYNTON, Dr. ASHBY, Dr. EWART, Dr. LEES, Dr. CARPENTER, Dr. R. B. MCVITTIE (Dublin), Dr. FISHER, Dr. LOGAN, and Dr. C. PINKERTON (Southport) took part in the discussion.

Note on the Age for Operating in Cleft Palate.

Mr. R. W. MURRAY (Liverpool) read a note on this subject. He said that the chief object for which such an operation was performed was that the power of speech might thus be rendered more perfect than it would otherwise be. At the same time he drew attention to the fact that the defect in articulation in these cases was not certainly due to the cleft of the palate but was in large measure due to the imperfect development of the nasal chambers. If the bones of the hard palate were involved the subsequent power of speech would never be perfect, even though an operation had been successfully performed during infancy. If, on the other hand, the soft palate alone was involved, articulation might subsequently be perfect. He drew special attention to the great importance of closing the cleft during the first two years of life and within this age limit the later the operation was performed the better.

The PRESIDENT pointed out that the development of the naso-pharynx must be encouraged as much as possible to induce correct speech and the sooner the cleft was closed the better. Therefore the earlier the operation was performed the more satisfactory was the result. In some cases he advocated operation even within a few days of birth.

Dr. GARROD THOMAS (Newport) supported the President in his opinion that an early operation should be undertaken.

Dr H. ASHBY (Manchester) pointed out that many a case of cleft palate succumbed after operation or even without operation owing to some concomitant brain deficiency.

THURSDAY, JULY 30TH.

Congenital Dislocation of the Hip.

Mr. F. F. BURGHARD (London) opened this discussion with a prefatory account of the changes usually met with in cases of congenital dislocation at various periods of life, specially referring to the rôle of each in preventing the reduction of the dislocation. The deficiency in the acetabulum favoured reluxation; the changes in the capsule—especially the anterior portion—opposed the return of the head of the bone into the acetabulum; the alteration in the angle of inclination of the neck to the shaft of the femur and the rotation of the long axis of the neck upon the vertical axis of the shaft were also changes of practical importance. He then described the different forms of congenital dislocation met with clinically and gave a short description of the methods at present in vogue for the treatment of this affection with regard to reduction of the dislocation by the method termed the "Hoffa-Lorenz operation." He thought that risk of ankylosis followed the extensive alterations produced in the articular surfaces, while the difficulty of obtaining a true radical or anatomical cure by Lorenz's bloodless method could be demonstrated by radiography. An open operation not involving interference with the conformation of the articular surfaces offered better chances.

Mr. ROBERT JONES (Liverpool) believed that more than one way existed for the cure of congenital dislocation of the hip and that the same method would not suit all cases. He thought that more good would come from a study of the causes of failure than from the most carefully compiled statistics. For years they had tried methods which had yielded an occasional success, such as extension and abduction in an abduction frame, osteotomy of the neck to correct anteversion, manipulations for reductions, and various forms of operation procedure. Neither the Hoffa nor the Lorenz modification appealed to him as stripping a joint of its cartilage and whittling the head of the former directly made for an ankylosing arthrodesis. The essential difference between the methods of Paci and Lorenz was in the recognition by Lorenz of the rudimentary character of the acetabulum and the necessity of enlarging it by direct pressure of bone. In support of the probability of this occurring Mr. Jones related that in a lad, aged 17 years, in whom he exsected the head of the femur for a traumatic dislocation he found an excellent attempt at the formation of an articulation. Until the visit of Lorenz he had no idea of the thoroughness of his manipulations and he at once saw why so many failures had occurred in this country. Since his visit Mr. Jones had operated on 38 cases, 34 of which were reduced as confirmed by palpation and x ray photographs, most of which were shown at the meeting. In four cases the neck of the femur was fractured and the shafts were transposed anteriorly. These were the only complications and with an increase of experience he thought should not occur. The causes of failure in reduction were fold of the capsule between the acetabulum and the head of the femur, sometimes constriction of the capsule, the importance of which was overrated, anteversion of the neck, and instability of the articulation due either to faulty head or rudimentary acetabulum. Of immense clinical importance was the question, "Can these defects be recognised clinically?" In reply he thought that on completion of reduction the surgeon could tell whether it would be permanent or not. If the hip in the act of being reduced gave the sensation experienced in the reduction of a traumatic case and if there were stability after reduction the prospects were good. Failure might safely be predicted when the femur slipped out of joint on the slightest provocation. In this last variety exploratory incision was called for to correct soft structure obstruction and to correct anteversion of the femoral neck. Anteversion could be diagnosed by radiography as well as by palpation. If operation were done Mr. Jones strongly advocated incision while the dislocation was reduced and if anteversion existed the performance of osteotomy of the shaft of the femur, the neck being held in position, as recommended by Schede and Bradford. He agreed with Mr. Burghard that it was best not to denude the cartilage, but in the worst cases, where operation was most called for on account of anatomical misfits, how was the head to be retained short of excavation? Mr. Jones, in view of the diverse opinions, intended to persevere with the Lorenz method as a routine, operating only in exceptional cases and after a sufficient lapse of time, and forming his own conclusions with regard to the final results.

LARYNGOLOGY AND OTOLOGY.

WEDNESDAY, JULY 29TH.

Dr. PATRICK WATSON WILLIAMS (Bristol), the President, delivered a short address on

The Position of Laryngology and Otology in the Medical Student's Curriculum.

After extending a very cordial welcome to the distinguished *confrères* who, in response to an invitation, had come from afar to take part in the work of the section, the President spoke of the necessity for the more systematic training of medical students in the clinical examination of the nose, the throat, and the ear, so that every qualified practitioner might be familiar with at least their commoner diseases and be able to interpret those phenomena which in their pathological significance directly bore on general

as an aid to

less valuable

on of a vocal cord paresis or paralysis often proved invaluable in the early diagnosis of central nerve disease, such as tabes dorsalis or bulbar paralysis, while every laryngologist knew full well that the larynx frequently yielded the one and only definite physical sign pointing to the existence of an intrathoracic aneurysm or other less common form of intrathoracic tumour. The distinction between a simple laryngitis and paresis of an otherwise healthy vocal cord was not a difficult matter and yet from want of a little familiarity with the laryngoscope it was often enough beyond the ken of the young practitioner. Therapeutical success in medicine depended especially on the recognition of serious disease in its earlier and more tractable stages. They were no longer content to await the development of the grosser

laryngeal tuberculosis before

adopting measures for its arre

realise the possible clinical import of simple hoarseness and should have sufficient knowledge of the larynx to be put on his guard ere the thickening of a cord or the localised tumefaction on a vocal process or in the interarytenoid fold had either spread locally or had masked the existence of an early pulmonary lesion till it progressed beyond the possibility of cure. Speaking of the radical extirpation of cancer he deplored the lamentable number of cases that passed beyond the hope of relief simply for want of earlier diagnosis. He went on to say that at the medical examinatio n for entry into the navy and army the teeth were carefully inspected. Many candidates were thrown out for some error of refraction that could be remedied by wearing spectacles or for some defect in chest measurement of little importance in after life, and so forth, yet unless the candidate was obviously deaf the existence of serious aural disease might escape observation. Quite recently a young gentleman directly after passing his medical examination for the army had consulted him on account of deafness which had been noticed for six or seven years. He had nerve deafness and could not hear the watch on contact on one side, whilst the hearing on *the other side was only $\frac{1}{10}$ths of the normal. He had touched* on one or two of the more striking points to show how essential some elementary knowledge of laryngology was in general practice and to support his plea that it should no

uate teaching was an

nvaluable as a means of extending the practitioner's knowledge of all the special and higher branches of medicine and surgery it was beyond the reach of many medical men and therefore it should not be relied upon as the chief, if not the only, means of obtaining elementary practice in the treatment of any regional diseases.

NAVY, ARMY, AND AMBULANCE.

WEDNESDAY, JULY 29TH.

Staff Surgeon **J. FALCONER HALL** communicated a paper on

The Water-supply for Landing Parties and Naval Brigades.

Owing to the many sudden and unexpected calls on the navy for landing parties in all parts of the world it was necessary to be always ready to meet such emergencies and the water-supply for a landing party was of vital importance to its success. In every landing party a certain number of men under a petty officer should be told off to attend to the water-supply and their sole duty should be to attend to its purification and transport. The men landed must be taught what had aptly been called "water discipline." It was quite easy to tell the men the risks they ran from drinking impure water, but it was much more difficult to prevent them doing so and to get them to have a little patience until a sound supply was procured. For drinking and cooking six pints per day ought to be the minimum and in hot climates this should be increased to at least nine pints and transport should be arranged to allow this quantity. Distillation was undoubtedly the best method of purifying water but this

e next

of the

The

chemical methods were practically useless, as for the most part they could not destroy active bacilli and were too complicated for the men to understand.

Fleet Surgeon **JOHN LLOYD THOMAS**, R.N., read a paper entitled

A Surgeon's Notes with the Naval Brigade in China.

The paper gave an account of the writer's experience with the Naval Brigade which formed part of the China field force for the relief of the Pekin Legation in 1900. The Naval Brigade numbered 535 officers and men and the proportion of sickness was 15 per cent. of the total strength, or 2·21 men sick per diem. Of these 9 per cent. were bowel complaints. There were five cases of enteric fever, one ending fatally. There were 12 cases of dysentery, with one death. The personal observation of the author went to prove that the trouble was due in nearly all cases to drinking bad water. It was almost impossible to control the impatience and carelessness of the men in drinking water and their choice usually was the handiest water. There were 31 cases of diarrhœa, the symptoms being of sudden onset, beginning with abdominal

The condition took the

tion and he was disposed

mechanical irritation of the mucous surfaces of the stomach and intestines and the presence of solid matters which had been ingested in a condition of suspension in various vehicles. The causes of nearly all these cases were ascribed first to water and secondly to food. The 31 cases did not represent the full number of those who suffered from this affliction; nearly everyone suffered from the "gripes," with six or seven stools during the 24 hours. Simple remedies sufficed to cure the complaint, whilst bland and nourishing food was given to replenish the system. If the cause of the affection was accepted as a purely mechanical and irritant one then the remedy should be to restrict the drinking water to that which had been carefully filtered. 12 cases of sunstroke were placed on the sick list because the men were incapacitated for an appreciable period. These did not include transient cases. Of the total cases two ended fatally. The treatment was water by the stomach and to the skin. When close to the river the patient was partially immersed or the head and body douched on the bank, with the legs dangling in the stream. This generally resulted in speedy recovery and the first sign of improvement was the desire for drink. The immediate after-treatment consisted of simple bland restoratives.

Lieutenant-Colonel **H. G. HATHAWAY**, R.A.M.C., communicated a paper entitled

Some Notes on a Mounted Bearer Company.

The author described a cart which he had invented, consisting of a light platform on strong springs over four wheels, the sides of the cart hinging down arranged after the fashion of an Irish car. The cart carried six sitting patients, three on each side, or two lying-down patients on stretchers. After describing the detachment of five men required for the service of these carts the author concluded by stating that it was unnecessary to have mounted bearer companies established in peace time, it being sufficient in his opinion to keep enough men in each squadron of cavalry for two such cart detachments always thoroughly instructed in first-aid to the wounded. Beyond that and the ability to ride nothing more was expected of them because they handed their patients over to the field hospitals for nursing at the first opportunity. For that reason it was not needful to employ men of the Royal Army Medical Corps on mounted bearer company duty.

In the discussion which followed on the three papers Lieutenant-Colonel **M. W. H. RUSSELL**, R.A.M.C., pointed out that care in regard to the drinking water was not an entirely new procedure on field service and detailed the routine followed in the Nile Expedition of 1884–85.

Deputy Inspector-General **H. M. ELLIS**, R.N., said that in regard to the water discipline of troops it was impossible for civilians who had never felt the stress of battle to realise the overwhelming temptation that came over troops when they felt that they were almost dying from thirst.

Surgeon-Major **J. ARNALLT JONES** (Aberavon) speaking as a volunteer surgeon, wished to congratulate Fleet-Surgeon Thomas on his paper.

Surgeon-General **G. J. H. EVATT**, R.A.M.C., spoke of the American system of extra food supply in addition to rations in the field.

Dr. H. E. L. CANNEY observed that in regard to the water-supply it would have been far easier to carry out the purification of water with the rapid sterilisers he had proposed to be used.

THURSDAY, JULY 30TH.

Surgeon-Captain G. ARBOUR STEPHENS (3rd Glamorgan Rifle Volunteers) read a paper entitled

Poverty of Attraction for Men to become Stretcher-bearers and the Consequent Inefficiency of that Section.

The value of the medical officer, he said, depended upon the material at his disposal, for however good he might be from a professional point of view without the needful assistance he was helpless. He stated that the volunteer regimental stretcher-bearers were an irregular squad of the most incompetent men ever detailed off for such work. That was the result of the absurdity of the system which prevailed and not the fault of the men. From each company two men were told off for ambulance work and each company officer, naturally retaining his best men, detailed for ambulance work the two most inefficient men he had. These men the medical officer was supposed to educate in a course of 12 lessons in anatomy, physiology, minor surgery, stretcher drill, and nursing. Good men would scarcely be considered very competent at the end of such a course and consequently the stretcher section was of absolutely no use whatever. There were about 223 volunteer regiments which gave a total volunteer ambulance strength of 3568 men, and this was in his opinion a sheer waste of red and blue serge. The author concluded by asking what there was to attract good men for the stretcher section? It was always to the rear of the regiment, the last into camp, and the last to have quarters allotted to it. The section received neither thanks nor prizes and good results could be hardly expected.

Brigade-Surgeon-Lieutenant-Colonel P. G. GILES (Welsh Border Brigade) communicated a paper entitled

Training Ambulance Men of Yeomanry.

He considered that difficulties would arise until some suitable means of removing a wounded yeoman was established. It had occurred to him that the best method would be a light ambulance cart near the ground that would accommodate itself to the movements of the horse without affecting the comfort of the patient and he described such an ambulance cart with an oblong hollow steel frame divided into three compartments In his opinion the transport of wounded men of mounted troops by means of riding supported either by another trooper or by means of straps and cords was very slow and unsatisfactory. Panniers were exceedingly difficult to load and really required two patients to balance properly. The method of carrying the wounded man in front of another trooper might be suitable for Victoria Cross competitions and had often been of use, but it was certainly unworthy of a place in the transport of the twentieth century.

Captain WILLIAM SHEEN, R.A.M.C. (Volunteers), read a paper entitled

Suggestions regarding the Personnel, Equipment, and Training of Medical Units attached to Volunteer Infantry Brigades.

He advocated that the medical unit attached to a volunteer infantry brigade should combine the functions of a bearer company and field hospital and this he believed was considered by many to be the best arrangement for the regular Royal Army Medical Corps. For such a unit he suggested the title of "Field Medical Company." A most useful article of equipment for a volunteer medical unit was a combined wagon and tortoise tent. He regarded as an essential improvement of the army ambulance wagon that it should be made to carry four patients lying down on stretchers. In training a volunteer medical unit the manual for the Royal Army Medical Corps should be looked upon as a guide and its drill varied to suit circumstances. He considered that far too much stress had been laid on the application of tourniquets. In not one of 342 cases of bullet and shell wounds admitted off the field into the Imperial Yeomanry Field Hospital was a tourniquet required. The author concluded by giving a short sketch of a typical Saturday afternoon field day for a medical unit.

In the discussion on the three papers which followed Mr. J. W. DAVIES (West Cross) said that proper instruction could only be carried out with the aid of a sergeant-instructor.

Surgeon-Captain A. E. LARKING (Folkestone) said that the only way to get together a good stretcher squad was to enlist men specially for ambulance work. He thought sooner or later that it would be found necessary to pay regimental medical officers on account of the expense entailed.

Surgeon-General EVATT said it had been decided that volunteer infantry brigade bearer companies were not Royal Army Medical Corps Volunteers.

Surgeon-General H. S. MUIR, C.B., (London) spoke of the efficiency of the Manchester Royal Army Medical Corps Volunteers, which corps he had had the opportunity of watching when principal medical officer of the North-West District a few years ago.

Surgeon-Major JONES said that the position of the volunteer regimental bearers was unsatisfactory. To enlist men directly into bearer sections meant a heavy tax on the purse of the medical officer.

Dr. CANNEY thought that the country should no longer make heavy financial demands on civilian medical men. He suggested that a commission should be formed representing volunteer and regular forces to advise the country on the point.

Captain SHEEN, in replying, said he was surprised to hear from Surgeon-General Evatt that volunteer infantry brigade bearer companies were not Royal Army Medical Corps volunteers. The men of the Welsh Volunteer Infantry Brigade bearer company were supplied with shoulder-straps bearing that designation, but these had recently been changed to straps bearing the lettering, "R.A.M.C., Welsh V."

Surgeon-Captain STEPHENS said that Surgeon-General Evatt had stated that if volunteer medical officers did their duty they would not court popularity with their combatant *confrères* but would reject a large number of men. He informed Surgeon-General Evatt that if that course were followed no volunteer regiment would be up to strength and the chance of getting regimental bearers would be reduced to a minimum.

FRIDAY, JULY 31ST.

Surgeon-General EVATT gave an address on

War Work.

His remarks on the military medical services constituted a sketch of the evolution of the regular, militia, and volunteer medical services in peace and war from the Crimean period through the unification period up to the present day, with suggestions as to the future developments of the military medical service in all its branches.

Surgeon-Major JONES referred to the valuable services rendered to volunteer medical aid by Surgeon-General Evatt, especially through his inducing the students of the great medical schools to join the volunteer bearer companies.

Inspector-General H. C. WOODS, C.V.O., C.B., R.N., in the course of his remarks informed those present that a scheme had been prepared for forming a reserve force of civilian medical officers for the Naval Reserve.

THE ANNUAL MUSEUM.

III.—SANITARY APPLIANCES, DISINFECTANTS, &c.

Sanitary appliances were represented chiefly in disinfectants, filters, stoves, special clothing, and sanitary ware. The Pure Enamel Bath Co., Limited, of Imperial Works, Bromley-by-Bow, London, E., exhibited two models of baths enamelled with a beautiful porcelain glaze. We have already shown that this glaze is free from lead and all materials susceptible to the action of sulphur baths or other medicated baths. A series of samples was exhibited showing the permanency of the enamel under tests including even the trial of alkalies and acids, hot and cold sea water, strong saline water, sulphur water, carbolic acid, effervescing baths, sulphuretted hydrogen water, and other mixtures employed in balneo-therapeutic practice. A specially high resistant enamel which was proof against acids and alkalies alike was also shown. The process is inexpensive and the result is an enamel amalgamated, so to speak, with the iron of the ordinary cast-iron bath in such a satisfactory way as to present the appearance of a porcelain bath. The gloss is good and the colour is pure. Close by Messrs. John Legg and Sons, engineers, of Swansea, exhibited a hot-water calorifier. This provides for a circulation of clean hot-water through a building already fitted with a hot-water installation. It consists of an iron cylinder through which the circulation of the ordinary hot-water-supply is maintained. In this cylinder is contained a hollow copper cone connected with distributing pipes The cone and the water inside it are heated by the water in the iron cylinder Circulation is readily established by means of an inlet and outlet pipe In a word, *the calorifier is a secondary heating apparatus in which the* heating of the water is effected by the hot water of the primary hot-water apparatus In this way water is not drawn off direct from the boiler The same firm show a hot-water radiator which can be swung like a gate from side to side in accordance with particular requirements Such an appliance is most useful in the hospital ward Messrs Slack and Brownlow of Abbey Hey, Gorton, near Manchester, exhibited a great variety of filters for high and low pressure and for domestic and industrial purposes The stoneware medium upon which the efficiency of this filter depends was reported upon by Dr G Sims Woodhead and Dr Cartwright Wood as impervious to germs when its working was kept under proper surveillance Messrs J Defries and Sons, Limited, of 146 and 147, Hound ditch, London, E C, showed a number of interesting hygienic appliances Amongst these were the Pasteur filters, a milk purifier, an appliance for sterilising excreta, and the equifex disinfectant appliances An excellent series of disinfectants in the form of powders, fluids, and soaps was presented to view on the stall of Messrs McDougall Brothers, of Manchester and 10, Mark lane, London, E C Amongst other things we noticed a bacteria powder and bacteria soap known as "kudo" which contain a very effective germicide. We are glad to note that this firm guarantee the bactericidal efficiency of their disinfectant preparations The izal disinfectants were shown in a number of forms at the stall of Messrs. Newton Chambers and Co, Limited, of Thorncliffe, near Sheffield Izal has been shown to be a very powerful germicide, outstripping, in fact, in this regard pure carbolic acid The Jeyes' Sanitary Compounds Co, Limited, of 64, Cannon street, London, E C, exhibited their well known creolin preparations as well as their disinfectant fluids, powder, and soap In addition to those described in this section there were a number of various disinfectant preparations shown by the firms which we mentioned last week as exhibiting drugs

IV.—SURGICAL INSTRUMENTS AND APPLIANCES

There was a good deal to be seen amongst the exhibits of the surgical instrument maker, including in particular some novel departures in regard to hospital outfits The exhibit of Messrs. Down Brothers, Limited, of 21, St. Thomas's street, London, S E, attracted considerable attention and consisted of a very large assortment of modern surgical instruments and a complete equipment of aseptic hospital furniture The exhibit was a somewhat comprehensive one and occupied a room to itself *Amongst other things shown was a portable* wooden operating table designed by Mr Jordan Lloyd The assortment of instruments exhibited by the Holborn Surgical Instrument Co, of 26, Thavies Inn, Holborn circus, London, E C, was an up to date one, comprising every kind of instrument used in modern surgery These included anæsthetic apparatus, gynæcological instruments, bone instruments, forceps, and so on The exhibit also of Messrs Mayer and Meltzer of 71, Great Portland street, London, W, attracted considerable interest It included hospital furniture, anæsthetic apparatus, and laryngological, rhinological, and aural instruments The electric lamp especially constructed for use in the theatre, ward, and consulting room should be mentioned as being of the most convenient description for the purpose (exploring cavities, &c) for which it is designed. Messrs Harry W Cox, Limited, of 9, 10, 11, Cursitor-street, Chancery lane, London, W C, exhibited a number of excellently designed electric appliances used in modern electro therapy, such as x ray apparatus and high frequency apparatus Messrs Arnold and Sons of West Smithfield, London, E C, showed a number of new surgical appliances, including some special applications of the electric light for the exploration of cavities Wood-wool preparations were the feature of the exhibit of the Sanitary Wood-wool Co Limited, of 26, Thavies Inn, Holborn-circus, London, E C This valuable antiseptic fabric has application in accouchement sheets surgical dressings, and vaccination pads. The patent appliances for the lame and the new support for flat foot of the O Connor Extension Co of 2, Bloomsbury-street, London, W C, are well and favourably known. The exhibit showed, moreover, that some new additions have been made in regard to improved appliances for accommodating weak or deformed feet. The Liverpool Lint Co of Mark street Mills, Netherfield road North, Liverpool, exhibited a variety of wools and lints for surgical use. Attention should be directed in particular to the "*impermiette*" bed *sheeting, which may* be washed *with boiling soap*-and *water* and *sterilised* without injury "Impermiette" is also described as a new substitute for jaconet Messrs George Gale and Sons, Limited, of Dominion Works, Birmingham, exhibited various forms of the Lawson Tait bedsteads which are well adapted for use in hospitals Electro therapeutic apparatus was shown by the Sanitas Electrical Company of 7A, Soho square, London, W Amongst these may be mentioned the latest appliances for the treatment of disease by light, by galvanism, and by high frequency currents Besides the Dowsing Radiant Heat and Light apparatus for the treatment of rheumatism and other diseases, the company of that name of 24, Budge row, Cannon street, London, E C, exhibited also the Scholder arthromotor, which is an ingeniously designed machine for applying mechano therapeutical and orthopædic treatment Apparatus for electrical treatment was also exhibited by the Electro Neurotone Company, Limited, of 26, Old Bond street, London, W, while Messrs Smith and Wade of 20, Baker street, London, W, showed the Wagner mica plate static machine which produces a current in an easy and convenient way that is especially adapted for the therapeutical application of electricity, as in x ray or high frequency work, and the production of ultra-violet light The same firm exhibited a multi nebuliser for producing exceedingly fine sprays The Longford Wire Co, of Warrington exhibited a number of bedsteads adapted for hospital use fitted with Wood's patent wire mattress Close by Messrs C Bellack and Co, of 12, March Arch, London, W, demonstrated vibration treatment by means of the Muschik vibrator Mr G H Zeal, of 82, Turnmill street London, E C, exhibited an admirable assortment of clinical thermometers, all designed to facilitate accuracy of observation The "repello" thermometer has already been described in THE LANCET The column of mercury, after an observation has been made, is brought back to its original level by simply pressing a flattened bulb at the top of the instrument. Mr N Bletchly, of 89, Northgate street, Gloucester, exhibited various designs of boots for abnormal conditions of the foot These included extension boots and shoes for shortened feet and legs, and for contracted heels, for club-foot and other deformities, as well as for gouty and rheumatic feet

V—MINERAL WATERS, BEVERAGES, &c

Natural mineral waters were somewhat in evidence this year, artificial waters being quite the exception Wales itself of course has several excellent mineral springs and amongst these is the remarkable sulphur water of Llanwrtyd The supply of water at this spa and health resort is abundant, whilst the amount of sulphuretted hydrogen contained in it exceeds any other water in Great Britain Specimens of the water in bottles were shown by the proprietors of the Dolecoed Spa, Llanwrtyd Wales A stall was devoted also to the exhibition of pictorial representations of the balneological practices carried out at the "Borough of Royal Leamington Spa" The authorities have spared no detail to make the royal pump room and bathing establishment equal in equipment socially as well as balneologically to continental health resorts. In a similar way photographs were shown of the important developments which have taken place at
Harrogate during recent ye.
mineral waters were shown
4, Stratford place Oxford str
naris water, exhibited specimens of the natural bitter water apenta, which is rich in the sulphates of magnesium and sodium. In addition to these natural mineral waters, the latter for medicinal purposes and the former an excellent adjunct for the table, specimens of the natural mineral water from the Johannis spring were exhibited. This water may be had also containing a definite added quantity of lithia or of potash Arabella, Limited, of 2A, Hay hill, Berkeley square, London, W, exhibited specimens of a natural mineral water belonging to the sulphated class. We have recently examined this water in THE LANCET laboratory and the results show that it contains the sulphates of soda and magnesia in desirable amount and ratio A curious point about this water is that in spite of its wealth of purgative salines it is not excessively bitter to the taste An excellent series of artificially aerated waters was shown by Camwal, Limited, Camwal Works, Bristol Illustrations were given of the methods adopted for insuring the purity and strength of the waters manufactured by this association.

VI.—PUBLICATIONS.

Publishers would appear to take continued interest in the exhibition and to regard it as a means of bringing modern publications to the notice of the profession. Amongst those who exhibited publications were Mr. Alfred R. Way of Swansea on behalf of Messrs. Cassell and Co., Limited, La Belle Sauvage, London, E.C.; Messrs. E. and J. Griffiths of High-street, Swansea, on behalf of Messrs. Macmillan and Co., London, and Messrs. Baillière, Tindall, and Cox of 8, Henrietta-street, Covent Garden, London, W.C.; Mr. H. K. Lewis of 136, Gower-street, London, W.C.; Messrs. W. B. Saunders and Co. of 9, Henrietta-street, Covent Garden, London, W.C.; and Messrs. Rebman, Limited of 129, Shaftesbury-avenue, Cambridge-circus, London, W.C.

VII.—MISCELLANEOUS.

Amongst the few exhibits of a miscellaneous character there was hardly one of strictly medical interest. In former years we have had occasion to describe under this heading a number of exhibits comprising motor-cars, carriages, and other objects of interest to medical men. The miscellaneous exhibits this year were, as far as we could see, of little medical interest at all and in some cases they were not in keeping with the general character of the museum.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

At a meeting of the council of the Metropolitan Hospital Sunday Fund which was held at the Mansion House on July 30th the report of the committee of distribution was passed, the payment of awards to hospitals and dispensaries was ordered, and an addition was made to the laws of the constitution. The report stated that

> The committee of distribution recommends awards to 209 institutions. The amount of collections, including interest from the Court of Chancery, to the present time is £60,900. The distribution of £58,386 11*s.* 8*d.* to 154 hospitals and to 56 dispensaries is recommended. This year 211 institutions, or seven more than last year, have made applications for grants from the funds. The committee is unable to recommend a grant this year to one hospital and one hospital was considered ineligible. In accordance with the resolution passed at the annual general meeting of constituents held at the Mansion House on Dec. 9th, 1902, the distribution committee has not included the outlay on repairs and improvements of buildings in arriving at the financial basis of each institution, so that the annual distribution will be wholly awarded for the "maintenance" of patients. The special attention of the committee of distribution has been directed to the constantly increasing expenditure of hospitals in the maintenance of patients. The average cost per week of each patient treated at 21 of the principal hospitals amounted to £1 16*s.* 6½*d.* in 1902. In 1897 the average was £1 13*s.* 1½*d.* In 1892 the average was £1 12*s.* 3*d.* Although at first sight the difference of 4*s.* 3½*d.* per week per occupied bed in these 21 hospitals does not seem very great, nevertheless it represents in these hospitals alone an increase of over £44,000 for a single year, *basing this calculation on the number* of beds occupied in the hospitals in question during the year 1902. In 1902 the cost per occupied bed per week varied between £1 1*s.* 3*d.* and £2 18*s.* 5*d.* in the hospitals referred to. While recognising the fact that the expense must necessarily have increased to some extent with the progress of scientific treatment and nursing the committee still thinks that the expense in some hospitals is higher than justified by these considerations. The committee has reduced the bases of award in 38 cases. Eleven deputations have attended the committee and after hearing their cases the final awards were determined. Their Majesties King Edward VII. and Queen Alexandra attended the Hospital Sunday service at St. Paul's Cathedral on Sunday afternoon, June 7th, on the understanding that the collections in the Cathedral on that Sunday would be for the "Metropolitan hospitals." It is satisfactory to state that the collections amounted to £5500. Mr. George Herring has again most liberally offered to give one-fourth to the amount collected in places of worship. The very inclement state of the weather on Hospital Sunday, June 14th, must have prevented many people from attending the services on that day, but it is gratifying to note that the amount so nearly approaches the collection of 1902 (Coronation year)—the record year of the Fund.

In the absence of the Lord Mayor Sir Sydney Waterlow, Vice-President of the Fund, took the chair and in moving the adoption of the report said that since the year 1872, when the Fund was founded, £1,239,933 had been collected and distributed. He thought that he was therefore justified in saying that the Fund was a success. The collection this year had been very satisfactory and he did not think that of all the 31 reports which he had had the pleasure of submitting to the council there had been one more satisfactory than that of 1903. More money had been collected in the churches and there was still more money to come in before the financial year closed. The collection had been increased in consequence of the attendance of the King and Queen at St. Paul's Cathedral and the confidence which His Majesty had in the administration of the Fund was shown by the fact that he had expressed his desire that the result of the offertory at St. Paul's Cathedral—namely, £5500—should be paid to the treasury of the Fund. This year there had been an increase in the number of contributing congregations. Collections were made at more than 200 places of worship and this showed, he thought, that the Fund rested on a solid basis which was never likely to be changed. He wished particularly to refer to the paragraph in the report which stated that the special attention of the committee of distribution had been directed to the constantly increasing expenditure of hospitals in the maintenance of patients. All the committee could do was to report on the matter and to leave it for consideration. It was difficult to determine the cost of out-patients, but it was desirable to have a conference of those interested in hospitals to consider the best method of arriving at some conclusion with regard to the matter, as the question materially affected estimates as to the cost of in-patients. He thought that the governors of hospitals should take into consideration the details of the cost per bed and see what a large sum could be saved if they could make a reduction of 1*s.* in the expenses of each bed. In conclusion, he remarked that Mr. George Herring, to whom they could never be too grateful, last year gave £11,575 towards the Fund and this year his contribution would be £11,600.

Prebendary Ridgeway, who seconded the adoption of the report, said that the churches which suffered least in regard to the falling-off of collections owing to the inclement weather on Hospital Sunday were those whose ministers took the trouble to bring the matter before their congregations prior to the date of the collection. At his church about £100 were lost owing to people who were not in church on account of the weather, but that deficit was more than made up by those who had had their attention called to Hospital Sunday beforehand. He therefore urged the importance of the clergy and ministers in all places of worship communicating with their congregations before the actual day of collection arrived.

Sir Henry Burdett drew attention to some of the figures in the report and said that he would like to know how the extra money had been distributed. As far as he could see it had not gone to dispensaries which were the oldest form of out-patient work and the most economical system of relief. Patients, too, were attended in their own homes and the members of the dispensary staff who might report sanitary defects to the health authorities thus became excellent hygienic ministers. Good was thus done quite apart from medical relief. He felt that the Fund had not done enough for the dispensaries.

Sir Sydney Waterlow said that no one could appreciate more than he did the work of the dispensaries and he should be glad if the committee could be authorised to deal more liberally with them, but the public subscribed to the Fund with the idea in their mind that the money which they gave would be given to hospitals.

Sir Edmund Hay Currie explained that the extra money had been given to those hospitals which were found to be the most economically conducted. Where the management of a hospital was not economical the basis of award was reduced and this had been done in 38 cases.

The report was then adopted.

On the motion of Archdeacon Sinclair, seconded by Mr. F. N. Norman, it was decided to add to Law IX. of the constitution, which reads—

> In the event of a congregational collection made on Hospital Sunday being given to a particular hospital, dispensary, or institution instead of being sent to the general fund the amount so sent shall be deducted from the grant made to that hospital, &c., and can in no case be included as forming part of the Fund—

The following:—

> In the further event of a particular hospital, dispensary, or institution fixing any day or days *in the week immediately preceding Hospital Sunday* in any year for the purpose of pressing the claims of such institution upon the public it shall be an instruction to the committee of distribution when determining the award to such institution to take into consideration the amount received from such an appeal and the loss, if any, resulting therefrom to this Fund.

Sir Stephen Mackenzie, Sir Sydney Waterlow, and Sir Henry Burdett took part in the discussion.

Mr. C. E. Tritton, M.P., moved a vote of thanks to Mr. George Herring "for his generous and continued interest in the Fund." This was seconded by the Rev. E. H. *Pearce* and carried with acclamation.

Votes of thanks were also passed to Sir Sydney Waterlow (chairman) and other members of the distribution committee, to the editors of newspapers, and to the Lord Mayor, who as president and treasurer of the Fund has devoted his valuable time to, and used his influence in the well-being of, the Fund.

THE LANCET.

LONDON: SATURDAY, AUGUST 8, 1903.

The Use of the Roentgen Rays in the Diagnosis of Pulmonary Disease.

THE accidental discovery of the x rays by Professor W. K. ROENTGEN of Würzburg towards the end of the year 1895 was soon followed by their application to medical and surgical uses in the diagnosis of injury and disease. The great advances which have been made in the production of these rays and their utilisation, more especially by the discovery of their action on a fluorescent screen composed of a layer of such a substance as barium platino-cyanide, have widened their sphere of usefulness to include not only diagnosis but also prognosis and treatment.

As early as 1896 Professor BOUCHARD applied them to the diagnosis of pulmonary disease and his observations have been confirmed and extended by a number of other observers, including Dr. HUGH WALSHAM in this country and Dr. F. H. WILLIAMS in America. In recent issues we have published two papers on this subject. The first of these is by Dr. J. F. HALLS DALLY[1] and comprises an account of the appearances of the normal chest and a critical study of the variations induced by pulmonary diseases. The second, by Dr. DAVID LAWSON and Mr. R HILL CROMBIE,[2] contains brief accounts of cases illustrating the use of the Roentgen rays in diagnosis, with reproductions of the radiographs or skiagrams obtained from them. Both these papers, affording as they do a useful *résumé* of the present methods of x-ray investigation in pulmonary disease, are of considerable interest and are obviously the outcome of a large practical experience of the subject. As in other departments of their use, the Roentgen rays can be utilised for diagnostic purposes in two ways: firstly, the so-called screen methods or radioscopic investigation, utilising the fluorescent properties of barium platino-cyanide under the influence of the rays, either in a dark room or by means of a specially contrived apparatus—the fluoroscope. The other method is the radiographic, in which the rays act upon a sensitive plate and a radiogram or skiagram is obtained on development and printing from the resulting negative. Comparing the value of the two methods most observers regard the radioscopic investigation as the more useful, since it is more rapid, more easy of application, and also allows the movements of the heart and the diaphragm to be directly observed, while in radiographic work, although a permanent record is obtained, yet if the exposure is at all prolonged some of the shadows which can be seen with the screen may be obliterated on the plate and are therefore not visible, and Dr. WILLIAMS in his book, "The Roentgen Rays in Medicine and Surgery," states that the record of some intrathoracic conditions by radiography, for example certain rapidly expansile aneurysms, cannot be hoped for until the instantaneous photography of the thorax is an accomplished fact. Dr. HALLS DALLY suggests a new nomenclature and draws a parallel between the results of x-ray investigation and the ordinary methods of physical examination; thus he would substitute the word "transradiancy" for translucency and this would correspond to normal resonance in percussion, brightness to hyper-resonance, faint shadow to impaired resonance, dense shadow to dulness, and opacity to absolute dulness. There are, however, certain shadows and lighter areas in the normal thorax of which cognisance must be taken and some of these are as yet imperfectly understood; thus in addition to the shadows produced by the ribs, the clavicles, and the scapulæ, and the well-known shadow of the heart and mediastinum, there are some faint and ill-defined streaks which Dr. HALLS DALLY calls the "pleuro-pericardial lines" and which he attributes to the junction of the parietal pleura with the mediastinum, while Dr. LAWSON and Mr. CROMBIE, adopting a suggestion of Professor D. J. CUNNINGHAM, regard them as due to the puckering of the outer edge of the pericardium during systole. The movements of the diaphragm can be observed by the radioscopic method and afford perhaps the most valuable information in the diagnosis of pulmonary disease by this means. Taking the average of a large number of normal cases Dr. HALLS DALLY finds that in quiet respiration the diaphragm moves half an inch on each side, but in maximum respiration the right side moves $2\frac{7}{8}$ inches and the left side $2\frac{5}{8}$ inches, apparently without the flattening which is usually described but with a bodily movement downwards called by Dr. WALSHAM "the piston movement."

So much for the normal appearances. In disease the chief departures from these, as might be expected, consist in the occurrence of shadows more or less dense where "transradiancy" or translucency should be observed, in diminished or altered movement of the diaphragm on one or both sides, and in alterations in the bony framework and its movements. It is claimed that the Roentgen rays may be of great use in the *diagnosis of pulmonary tuberculosis*, pneumonia, pleurisy with effusion, serous or purulent, gangrene of the lung, emphysema, and pneumothorax, but it is practically only in early pulmonary tuberculosis that the method at present seems likely to offer any information commensurate with the work entailed by its application. From the accounts published, not only in the two papers already referred to, but also by Dr. WILLIAMS in his book and by Dr. BONNET-LYON of Paris, it would seem that a lesion in the lung giving rise to no physical signs or only at most to some slight departure from the normal may yet give definite evidence of its presence by a diminished movement of the diaphragm or by some faint shadow at the site of the deposit, the former being the earlier, and according to the advocates of this method the earliest sign yet obtainable, and Dr. HALLS DALLY in his summary concludes that the Roentgen rays form an important adjunct to the other methods of physical examination and that by their means pulmonary tuberculosis can be diagnosed at an earlier stage than by any other means at our disposal. At the first part of these conclusions probably few would be disposed to cavil, but, after all, the ultimate test of the tuberculous nature of a pulmonary disease, as Dr. HALLS DALLY himself admits, can only be the discovery of the tubercle bacilli in the sputum, and although the early diagnosis of tuberculosis is a most important matter, and although the rays may render the inference of tuberculous deposit probable at an earlier period than other methods and so enable valuable time to be gained, yet even the rays in such early stages give no absolutely unequivocal indication. In other words, x-ray investigation, at present in an experimental stage, is a useful addition to other methods, more especially as an appeal in the case of certain difficult and doubtful cases, but that it can take a place as a routine procedure of examination of the chest is hardly possible at present. That it may do so when methods and apparatus are simplified is more than probable. In any case the study of the method, of its uses and its limitations, as in the two articles mentioned, is on all grounds to be commended.

---

[1] THE LANCET, June 27th, 1903, p. 1801.

[2] THE LANCET, July 25th, 1903, p. 212.

The Home Secretary and the So-called Anti-Vivisection Movement.

THE plain and well-worded rebuke recently administered by the Home Secretary, Mr. AKERS-DOUGLAS, to a deputation which came before him to protest against the increase of vivisection will be read with satisfaction by all who can take an unprejudiced view of the aims and methods of scientific progress. The deputation represented the Parliamentary Association of the British Union for the Abolition of Vivisection, and its objects were to ask for the total abolition of vivisection and to demonstrate the uselessness of looking for any genuine advance of medical science by vivisection. The first of these we imagine to be much easier of attainment than the second; anybody can ask for the moon, but not everybody can prove that the moon is made of cheese. It will be no light task for the Parliamentary Association of the British Union for the Abolition of Vivisection, or for any other body even with a longer title, to demonstrate the necessary futility of all experimental work on the lower animals; but it is fairly easy to show by internal evidence that no member of such a body will ever believe in a scientific advance made by steps which run contrary to the particular fads which govern his judgment. Anti-vivisectionists, as most other people of extreme views on one issue, are singularly blind to demonstrations of fact or to arguments of reason. Their gaze is fixed with such an intentness upon the one ideal that no rays of truth from surrounding objects or circumstances can reach the retina of their judgment. Their vision has no periphery at all. It is useless to argue with such that a man may be a physiologist and still retain the ordinary feelings of a human being towards the lower animals. They know better and will cruelly libel a number of educated men in support of their creed and in proof of the fine quality of their mercifulness.

A better instance of the singular way in which the judgment can be warped by violent opinions could hardly be forthcoming than that furnished by some remarks made by one of the speakers in the course of the interview between the deputation and Mr. AKERS-DOUGLAS. Sir JOHN ROLLESTON appears to have stated that "they had it on the highest authority that experiments on animals were useless to determine or direct the medical treatment of man and were generally misleading. It had been admitted by Sir FREDERICK TREVES that his experiments on animals had not been of service, for when he went out to South Africa and operated upon the soldiers the results obtained were quite different." What Sir JOHN ROLLESTON was driving at in this observation it is impossible to guess, but the juxtaposition has an almost childish quaintness. It would be nearly as sensible to say that the British soldier does not believe in roast beef since the war in South Africa because he found that his appetite was quite differently appeased there by rations of biltong. Sir FREDERICK TREVES has decisively rebutted the insinuation that he is opposed to vivisection, while another contention raised by the deputation also met with well-earned contradiction from the Home Secretary. The deputation pleaded for increase of inspectors under the Act and declared that at present inspectors are appointed by approved vivisectionists naturally inclined towards vivisection. Mr. AKERS-DOUGLAS contradicted this statement and showed that the inspectors are appointed by the Secretary of State and asserted that it was "not his practice, nor was it the practice of his predecessors, to go entirely into the ranks of one party or of the other for the election of inspectors." It must also be pointed out to the Parliamentary Association of the British Union for the Abolition of Vivisection that the Home Secretary's choice of individuals to serve as inspectors is somewhat limited when he has to look round for representatives of the antivivisection school of thought. The opponents to scientific progress are not important people numerically or intellectually, and do not offer, therefore, among their *personnel* much opportunity for the selection of inspectors under an Act of Parliament.

The deputation seems to have made but a slender effort in the only direction in which success would have been of any importance to their cause. They failed signally to show in any impressive way whatever that vivisection is of no use or that there is other good cause for its total abolition. That there is a certain mass of sentimental opposition to the practice of vivisection the deputation did, indeed, bear evidence. But evidence to this effect was not required. We are all aware of this sentimental opposition, and we are all in sympathy with it so far as it represents the humane desire to avoid cruelty towards the lower animals. Mr. AKERS-DOUGLAS'S reply was a model of reasonable support of scientific freedom, and furnished complete evidence that the Home Secretary is alive to those truths which so entirely escape the grasp of the anti-vivisectionist. He would, he said, neither introduce a Bill for the abolition of vivisection nor advise the Government to do so nor vote for such a Bill were it brought before Parliament. He maintained that the class of physiological and pathological work known as vivisection is an important aid to medical science and said that "however much they all disliked the incidental suffering which might follow experiments the result is justified in the well-being of the country at large." We trust that the reception of this deputation by Mr. Akers-Douglas may lead some of the sentimental upholders of antivivisection to consider the situation a little and to ask themselves whether all the wisdom and humanity in the country are confined to their own clique.

The King's Visit to Ireland.

The King's tour through Ireland, from his entrance at Kingstown on July 21st to his departure from Cork on August 1st, was a triumphant success. All who came into intimate contact with the King were charmed with his geniality and courtesy of manner. His kindly smile and gracious demeanour put everyone at his ease. Over and over again Edward the Seventh showed himself to be gifted with the utmost tact and with the most human sympathies. The Queen, who is such a universal favourite, won the hearts of the Irish by her grace, beauty, and kindly interest in suffering and poverty. The social and political bearings of this tour concern us in The Lancet to this extent, that as good citizens we desire earnestly to see peace and prosperity prevail in these islands, and we join with His Majesty in hoping that a brighter day is dawning upon Ireland. We feel with him, as he so admirably expresses it in his address "to my Irish people," that the realisation of this day will depend largely "upon the steady development of self-reliance and coöperation, upon better and more practical education, upon the growth of industrial and commercial enterprise, and upon that increase of mutual toleration and respect which the responsibility my Irish people now enjoy in the public administration of their local affairs is well fitted to teach."

The medical aspects of Their Majesties' extremely busy visit to Ireland are important. The King and Queen during their sojourn in Ireland made it very plain how much they are interested in hospitals and in the anxious work done by members of the medical profession. In Dublin Her Majesty went to the Hospital for the Dying, while in Belfast and in Derry the memory of gracious visits to the hospitals will long remain. In replying to the address presented to him, in opening the Royal Victoria Hospital, Belfast, His Majesty returned thanks on behalf of himself and the Queen for the opportunity given them of visiting the institution "which has for me a personal interest because of its association with the name of my beloved mother and after the proceedings of to-day with the memory of our ever to be lamented son." The King and Queen then most carefully inspected this new hospital and no one who was present will ever forget the simple but beautiful ceremony in the women's ward when Her Majesty named it the "Clarence," in affectionate remembrance of her son. We are in a position to record that Their Majesties regard the Royal Victoria Hospital, Belfast, "as one of the finest and most up-to-date hospitals they have visited." In laying the memorial stone of the new buildings of the Derry Infirmary, the King in reply to an address indicated very clearly his views as to the benefits of hospitals:—

> It has given the Queen and myself great pleasure to visit an institution devoted to the relief of the suffering poor of the city and county of Londonderry. I am pleased to hear that your Infirmary has been productive of so much benefit in the past and that the liberality of your fellow-citizens is enabling you to meet the growing requirements of surgical and medical science. There is no field in which public generosity can effect greater good than in bringing within the reach of those unable to procure it for themselves the means which modern science affords for the alleviation of suffering and the cure of disease. I may, in conclusion, say that it always affords me great gratification to be in any way instrumental in promoting the interests of institutions like yours.

The English Royal family have been famed for their appreciation of the medical profession. King Edward has in particular always shown the deepest sympathy with our calling, and his serious illnesses have intensified this feeling. During his recent visit to Ireland there were no people to whom he was more courteous than the members of the medical staff of the hospitals which he visited, while in the apportionment of honours in connexion with the Royal visit medical men have been generously treated.

If the pointed and practical observations that the King and the Queen made during their visits to hospitals, and the questions which they asked, showed what a thorough and specialised knowledge they have of hospital administration another special feature of this Royal visit to Ireland must not be forgotten. We refer to the great effort made by Their Majesties to know the surroundings of the poor. Their visits to the slums of Dublin and their close inspection of the peasants of Connemara will, we are sure, be turned to practical account in suggesting measures for improving the condition of the submerged population of the country. We look with confidence to far-reaching effects from the visit of the King and Queen to Ireland.

Annotations.

"Ne quid nimis."

CANCER RESEARCH.

The first annual meeting of the general committee of the Cancer Research Fund was held on July 30th in circumstances which were decidedly encouraging to the movement. In the unavoidable absence of H.R.H. the Prince of Wales, who is President of the Fund, the Prime Minister took the chair, and in reply to a vote of thanks delivered an admirable address, showing genuine appreciation of the magnitude and the difficulties of the task which the committee is undertaking. No precisely similar research has, perhaps, ever been attempted, while the mere fact of the project being favourably regarded in the highest quarters, both social and political, shows that the public has become of late more conversant with the scientific views and possibilities of medicine. The public now recognises that important improvements are gradually being made in the diagnosis and treatment of disease and that in many directions old rules of thumb are being superseded by logical processes of therapy founded upon exhaustive methods of research. But the task that lies before the committee intrusted with the prosecution of research into the cause of cancer differs from all previous collective researches into the natural history or pathology of a disease inasmuch as its object is the solving of a problem about which nothing definite is known save that up to the present time the efforts of the foremost authorities in anatomy, histology, and micro-biology have failed to cast any light on it. Hence the appropriateness of Mr. Balfour's warning that immediate results can hardly be expected. Sir William S. Church had, indeed, already indicated as much by pointing out that the committee intended to undertake cattle-breeding on a small scale with the view of ascertaining how far the malignant diseases of domestic animals were transmissible. The operations of the committee will therefore not be confined to a restricted area, but will cover a wide field, a distribution of work which we have already advocated[1] when commenting on the scheme whilst it was still in its initial stage. There is little room for hoping that any important addition to our present knowledge of the pathology of cancer can be made without the exercise of much patient application on the part of highly trained workers, dextrous in utilising portions of the work of their predecessors. The most important addition made of late years to the instrumental resources of the surgeon was the discovery of the x rays by Professor Roentgen in the vicinity of tubes of high vacuum traversed by a current of electricity; these vacuum tubes, however, were by no means new, they had already been used for more than 15 years by Sir William Crookes and were universally known by his name. Similarly it may be that the solution of the problem of the origin of malignant disease lies close to our hands, perhaps half-discovered. But, on the other hand, the absence of any certainty in any direction may make the process of research a very long one; all sorts of clues may have to be followed, and the experiences of numberless observers to be codified, before the right track is found. It is well that the public should understand this and lay to heart Mr. Balfour's warning against impatience. The financial position of the fund decidedly requires strengthening and the total amount —some £43,000—still wanting for the completion of the endowment ought not to be long withheld, considering that the question involved is one of extreme importance in connexion with public and individual health.

RADIO-ACTIVE ATMOSPHERIC AIR.

Radio-activity would appear to be a universal property. Recent researches have at any rate shown that radio-active emanations exist in the atmosphere and that their source is probably the soil. The air abstracted by simple suction from the soil is found to be charged with active emanations, and similarly the air of cellars and underground places exhibits this remarkable property. Yet another interesting example is that of the natural carbonic acid gas which is evolved in districts along the Rhine which shows marked radio-activity, but some days after its liberation from the earth the gas becomes inactive and behaves like artificial carbon dioxide generated from carbonates by the addition of acids. It is well known, again, that the gases evolved in the thermal waters of Bath contain an important quantity of helium, and Professor Dewar is employing these waters as a source of this mysterious element for experimental work. It would be interesting to determine whether the gases evolved from the thermal springs of Bath are radio-active. In all probability they are. That being so, has helium anything to do with the phenomenon? Quite recently Sir William Huggins and his gifted wife Lady Huggins proved, by examining spectroscopically the light emitted directly by a radium salt at ordinary temperatures, that many of the lines coincided with the spectrum of helium. Again, Professor Rutherford obtained evidence in favour of the view that in the very slow break up of radium helium appears to be one of the products evolved. Still more recently Sir William Ramsay and Mr. F. Soddy succeeded in detecting helium by the spectroscope in the gases extracted from the radium salt. When Sir William Ramsay confesses that he is as much in the dark about it as anyone it is wise perhaps to wait for the results of further investigation before attempting to give any explanation of this singular phenomenon. It is, however, a very remarkable circumstance, considering the series of intricate chemical operations through which radium must pass before it is isolated in a more or less perfect condition, that apparently it should generate helium in some inexplicable way. The fact remains that there is a continuous production of helium from radium. It would be comparatively easy therefore to account for the air showing in general radio-active properties since the property is, so to speak, easily infectious. There are immense stores of radio-active material in the earth and in fact the whole globe is probably a radio-active sphere. The fact that natural gases escaping from the earth show a marked degree of radio-activity might be useful perhaps in differentiating natural from artificial aerated waters. Different meteorological conditions appear to determine different degrees of radio-activity of the air. Thus considerable activity is excited during fog, while in cold, frosty weather the activity of the air is very high. Again, the direction of the wind influences the radio-activity of the air. With the wind in the south and east the activity is about the same; with the wind in the north and west the activity is much lower. A fall of the barometer leads to increased activity probably because radio-active air is withdrawn from the soil owing to the reduced pressure. Altogether, it would appear that the discovery of this remarkable property of radio-activity presents a vast field for exploration. We ventured to think some years ago that such would be the case as soon as sufficient radio-active material could be isolated. The discovery of the properties of radium and helium promise to lift the great veil of nature high indeed, and the patient, laborious scientific research which has led to this result must not be forgotten.

THE ARMY ESTIMATES.

The recent discussion of the Army Estimates in the House of Commons possessed many points of medical interest. Taking it altogether Mr. Brodrick has been subjected to a long and trying ordeal of criticism of all sorts during his term of office, and he must have hailed the wholesale diversion of public attention to the tariff question with no little relief and satisfaction. Touching the subject of the soldiers' rations we consider that what Lord Stanley and Mr. Brodrick had to say seemed to be weak and inconclusive. It was alleged, and the allegation was not denied, that the recruit under training was not as well fed as the soldier when trained. Seeing that army recruits are young, immature, and growing lads and that they have as a rule been underfed previously to enlistment and possess keen appetites, we should have thought that if anything they required to be better, and not less well, fed than trained soldiers. That would seem to us to be the conclusion to be derived from physiological considerations and to be also entirely in accordance with ordinary experience. It is scarcely to be expected that a recruit will expend his daily pay in order to supplement his rations, or that, if ready to do this, the food so purchased will be of the most suitable and substantial kind. We have no doubt that, personally speaking, the War Minister is really of opinion that the recruit should not be stinted in regard to his supply of nourishing food, and that the State ought to furnish the young soldier with all he needs. But there at once arises the question of expense which would be considerable. It would nevertheless repay the State to incur the cost in the interest of the army and of all concerned. We are ready to hope and believe that, speaking generally as regards the soldier's accommodation and personal hygiene and comfort, considerable progress has taken, and is still taking, place. Mr. Bardett-Coutts in reference to the vote of £530,000 for the medical establishment, spoke about the reforms and changes which had been introduced in regard to the medical department, and commended the association of the civilian with the military element on the Advisory Board as a wise principle. But he thought that the relations of the two elements might be more clearly defined with the view of facilitating administration and avoiding friction. He likewise called attention to the very inadequate allowance made to the civil medical members on the Board. Mr. Brodrick's speech on the occasion in question will, we think, be generally regarded as satisfactory. It was, as is usual with Mr. Brodrick, optimistic in tone. He stated that at the last examination there were 72 candidates for 30 vacancies, some of the candidates having held places as house surgeons in the best hospitals in London. He fully recognised the services which Mr. Bardett-Coutts had rendered, eulogised the medical profession for the great and generous aid which he had received from several of its most eminent members, and dwelt upon the numerous beneficial changes which had already taken place in various directions and on others which are, he said, forthcoming. We hope that Mr. Brodrick's sanguine views will have quick justification.

HOUR-GLASS STOMACH.

ONE of the most important results of the healing of a gastric ulcer is the narrowing of the lumen to which it gives rise. Should this occur at the pyloric opening a general dilatation of the stomach will result; if, however, the contraction is nearer the middle of the viscus an "hour glass" stomach will be formed, the stomach consisting of two cavities communicating with one another by a narrow orifice. This leads to a most troublesome form of dyspepsia hardly remediable by any medicinal or dietetic treatment, but surgery, by making a free communication between the two loculi of the stomach, usually succeeds in removing completely all the symptoms. The condition is so well recognised now that it is often possible to diagnose it before operation. In the present number of THE LANCET we publish a case which was under the care of Mr. B. G. A. Moynihan in the Leeds General Infirmary. The diagnosis of hour-glass stomach was definitely made and when the abdomen was opened this condition was found, but further examination revealed that the stomach was constricted in two places, a triloculated or trifid stomach being formed. Operation completely relieved the patient. The rarity of the case is great and it is, we believe, the first case of trifid stomach on which an operation has been performed. It demonstrates clearly the great importance of examining the whole stomach in such cases, for if the third pouch had not been found the operation would have failed to relieve the patient. We congratulate Mr. Moynihan on this very interesting and satisfactory case.

THE HEALTH OF THE HOLDERS OF LONDON COUNTY COUNCIL SCHOLARSHIPS.

THE brief reports which have been drawn up by Dr. L. C. Thorne Thorne and Dr. F. May Dickinson Berry on the physical condition of the holders of London County Council scholarships for the past years provide a satisfactory record and much interesting information. It is instructive to note that the physical development of these clever children, both boys and girls, is distinctly above the average as measured by the standard of height and by the standard of chest measurement. The analysis of the physical examination of training college scholars (boys) is decidedly superior to that of the junior and intermediate scholars, while as regards the examination of the girls the most noteworthy point is the number of cases which display weakness of the muscles of the back with a tendency to lateral curvature. This latter abnormality has led to the suggestion on the part of Dr. Berry that more ought to be done for girls in elementary schools to develop the muscles of the back by physical exercises and gymnastics. The fact that so large a number of these intellectually superior children should give evidence of albuminuria is a point which requires explanation—15 per cent. of the junior scholars (boys) had albumin in the urine, while of the intermediate and commercial scholars 25 per cent. showed the same pathological condition. In the case of girls the juniors showed about the same percentage of cases of albuminuria, while the intermediate scholars were only affected to the extent of about 14 per cent. Dr. Berry apparently regards a slight degree of albuminuria as a matter of no great importance. The clinical significance of so-called physiological, cyclic, or intermittent albuminuria in children is little understood. It appears, however, to be more common among those of precocious mental development and those generally of a nervous temperament. The subsequent history of the subjects of examination should not be difficult to follow and it would be most interesting and instructive to learn whether the independent appearance of albumin in the urine of children apart from symptoms of organic disease of the kidneys is a precursor of more serious disease at a later period of life. Several cases of stammering, both in girls and in boys, are recorded and the number of children who have been found to be suffering from defective hearing, defective eyesight, and adenoid growths in the naso-pharynx is suggestive that even among the superior classes of schoolboy, from which most of these scholars are drawn, there is great need to have these conditions treated at an early age, when there are reasonable prospects of preventing serious and permanent damage.

THE MOTOR-CAR BILL.

THE Motor-car Bill was read in the House of Commons on the night of August 4th for the second time, but only after Mr. Long had consented to introduce a clause providing for a speed limit. The question of what "speed limit" is to mean is to be left to the Committee stage, but it has been indicated that there will be two penalties under the Bill. The one will be for driving at a speed exceeding the maximum allowed and the other for driving at such a speed as to be dangerous to the public. The latter offence may be punished by imprisonment but the former will be met with a fine, and we hope that the fines will be heavy, especially where any attempt to resist authority is shown. What, for instance, is the use of fining the owner of Holland House a few pounds? As to speed, our own opinion is generally in conformity with that expressed by Sir Philip Muntz—namely, that no motor-car should be allowed to travel at a faster rate than first-class horse traffic, and we think that this is a view that will be very generally shared by the medical profession—a class in whose hands the motor-car, rightly used, may be a real blessing to rural communities. Our present highways were laid out for horse traffic, and in the palmy days of coaching the best coaches travelled at a rate of ten miles per hour including stoppages. If a motor-car goes faster than 15 or 18 miles per hour the road is being used, very generally, for a purpose which its angles and gradients and breadth do not suit. Moreover, it is not merely danger to traffic, both pedestrian and vehicular, which motor-cars bring about; they cut up the surface of the roads, while the annoyance, to use no stronger term, caused by the dust, the smell, and the noise make many a country residence, the grounds of which border on a highway, perfectly uninhabitable. Here it is the heavy car designed to go at a furious pace, and generally going it, which does the harm, especially when driven by that class of motorist whom Sir Fortescue Flannery designated in the House of Commons, with most happy phrasing and legitimate loathing, as a "road hog." The motor-car of proper construction for the roads and driven by competent and respectable persons, ought to be a source of benefit to many members of the community, but it must be used in such a manner as not to interfere with the enjoyment of the roads, so as not to destroy property, and, above all things, so as not to endanger life. We hope that the Government will be able to frame and to pass a measure securing these things.

THE METROPOLITAN HOSPITAL SUNDAY FUND AND THE APPEALS OF HOSPITALS TO THE PUBLIC.

A MEETING of the Metropolitan Hospital Sunday Fund was held at the Mansion House on July 30th (see p. 410 of this issue) when an addition was made to Law IX. of the constitution which appears to us to be of considerable significance. The new article of the constitution empowers the committee of distribution, when determining awards to institutions that have made appeals to the public immediately preceding Hospital Sunday, to take into consideration the amount received from such appeals and the loss, if any, which the Fund may have thereby sustained. Our readers will remember that appeals were made on behalf of certain hospitals this year in the weeks immediately previous to Hospital Sunday and it is probable that the responses to these appeals to some extent stopped the flow of charity to the Fund. Again, the council of the Metropolitan Hospital Sunday Fund looks to the press for special aid during the actual week of collection and during the preceding days, but the columns of many papers had been recently filled with other appeals to the public to make gifts to certain particular institutions, with the result that these papers could not extend to the Fund the same amount of support which they have given in other years. We feel sure that the hospitals which made appeals at an unfortunate date this year will not do so again, but it is well that the committee of distribution should mark its sense of the injustice of any charity receiving at the same date a special donation from the public and a share of the general charity. The Metropolitan Hospital Sunday Fund has now been in existence for more than three decades and the middle week in June has become associated in the public mind with a collection for the Fund. If appeals are made to the public at that particular season of the year by individual hospitals confusion may arise and charity may be diverted from its intended object.

THE DISTRIBUTION OF PLAGUE.

As regards the Cape Colony the medical officer of health states that for the week ending July 11th the condition of the various places mentioned below was as follows. At Port Elizabeth 2 cases of plague were discovered during the week—namely, 1 native male (found dead) on July 7th and 1 coloured male on the 11th. At the Plague Hospital 1 coloured male was discharged during the week, leaving 6 cases under treatment. Plague-infected rats continued to be found in the town. At East London 1 case of plague was discovered—namely, a native female (found dead) on July 5th. At the Plague Hospital 1 native male was discharged during the week, leaving 4 cases under treatment. At King William's Town no case of plague was discovered. At the Plague Hospital 1 European male and 1 coloured male were discharged, leaving 3 cases under treatment. Plague-infected rats continued to be found in the town. Neither at Graaff-Reinet nor at Burghersdorp was any case of plague in man or in rodents discovered during the week. At Queenstown 3 cases of plague were discovered—namely, 1 native female on July 5th who died on the following day, 1 native female (found dead) on the 6th, and 1 native male (found dead) on the 7th. No patients were under treatment in the Plague Hospital. Neither at Stockenstroom not at Riversdale was any case of plague in man or in animal discovered during the week. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on July 31st states that for the week ending July 30th there were 12 cases of plague and 8 deaths from the disease. In Hong-Kong, a telegram from the Governor received at the Colonial Office on July 27th states that for the week ending July 25th there were 13 cases of plague and 11 deaths from the disease.

CADGE OF NORWICH.

A MOVEMENT has been set on foot to perpetuate the memory of the late Mr. William Cadge of Norwich in some permanent form. Accordingly, at a meeting held on July 22nd, at the request of Mr. William H. Day, chairman of the committee, and attended by some of the professional friends of the late Mr. Cadge, it was resolved that either a memorial window or brass in the chapel of the Norfolk and Norwich Hospital would be suitable, that subscriptions should be confined to his professional brethren, and that these should be limited to one guinea. Any medical man who desires to participate in the above is requested to forward his subscription to Dr. M. Beverley, Norwich, who is the treasurer of the fund.

TUBERCULOSIS IN THE EASTERN COUNTIES IDIOT ASYLUM.

ALTHOUGH the Idiot Asylum at Colchester is not situated in exactly rural surroundings there is nothing about its exterior to suggest to the traveller on the Great Eastern Railway as he passes Colchester station that the institution is either a culture ground for the tubercle bacillus or a home for dying tuberculous patients. But the annual report for Colchester for the year 1902, which is written by Dr. Edward Chichester, who was then acting as medical officer of health, suggests that there may be something about the institution which requires investigation at the hands of a competent committee composed largely of medical men. During 1902 there were 16 deaths from tuberculosis registered in the institution. This isolated fact conveys nothing, but when it is considered in relation to the circumstance that there were only 23 deaths from all causes it is apparent that the tubercle bacillus was responsible for no less than 69·5 per cent. of the total. This seems to require some explanation, more particularly when it appears that the total population of the asylum is only about 300. If this number really represents the total population for the year we have 16 deaths from tuberculosis in an asylum population of 300, as compared with only 67 deaths from tuberculosis in the remainder of the Colchester population of some 37,000. We shall hardly be surprised to learn that the subscribers to this institution are anxious to ascertain what are the actual facts—whether, for instance, the figures are trustworthy and the inferences sound, and, if so, what steps are being taken to ascertain the cause of this excessive incidence of tuberculosis upon the inmates.

THE CHRISTIAN HOSPITAL OF CHICAGO.

THE United States is the country in which, *par excellence*, flourish diploma-selling institutions of all sorts and kinds. Many of the more notorious of these have been abolished, but there yet remain several where degrees may be bought for a pecuniary consideration. An institution has been set going recently in Chicago which embodies in its rules of membership many objectionable features. This institution is called the Christian Hospital and includes among the members of its medical and surgical staff some well-known medical men of Chicago. The president of the staff, indeed, is a surgeon of world-wide fame. The objects which the originators of the Christian Hospital hope to attain by its establishment are set forth in the circular issued by them to the medical profession as follows. "Our certificate of membership is artistically designed and executed in the highest style of the lithographer's art, neatly framed, and hung on the walls of your reception room it imparts confidence to all visitors and patients and is a much stronger drawing card than an ordinary diploma as it indicates a higher attainment. We furnish free with each of our certificates a solid gold lapel button of special Red Cross design in enamel and the words, 'Christian Hospital, Chicago,' in circular form around the red cross; also a neat pocket membership ticket. This alone if displayed judiciously will bring more dollars annually than the cost of your membership. We will agree to pay you a cash commission of 50 per cent. of all surgical fees and 25 per cent. of all medical fees received from patients you bring or send to us. This, of course, will be held strictly private and confidential. Your professional interests as well as our own demand this." The last clause contains the essence of the whole scheme, which is to induce medical men to send patients to the institution, the bait being the promise of a division of fees. The American Medical Association at its recent meeting[1] in its new "Principles of Medical Ethics" laid special stress upon the question of division of fees and strongly deprecated the custom. In the face of this expression of opinion it is hard to see how medical men of note can lend their names to the furtherance of such an institution as the "Christian Hospital" of Chicago.

FOOD AND DRINK SWINDLES.

IT has long been known that bees exhibit a preference for genuine cane sugar and unless starving they will not touch the beet substitute at all. This fact may or may not have a physiological significance; it depends, it seems to us, upon the purity of the sugar. There is no evidence, as far as we know, that cane sugar is physiologically or dietetically superior to maple sugar. When, however, it can be shown that the sugar is impure either can obviously be injurious to health. And in this regard beet sugar is much more likely to contain injurious impurities than genuine cane sugar, for the former has to be "faked" in order that it may more closely resemble the latter. Tin salts are admittedly employed to give yellow crystals the appearance of Demerara crystals and aniline dyes are used again to correct the yellowness of the crystals and to give them the appearance of white loaf sugar. All such devices are certain to be physiologically mischievous; they are calculated to interfere with the natural condition of the sugar in which it is best suited for physiological requirements. This is typical of the frauds commonly practised in regard to articles of food and drink at the present day. "Substitution" is a very great modern evil and those who encourage this practice and thrive upon it should be punished very severely and sufficiently to act as a deterrent to the continuation of it. The creed of the substitute-monger is always that the substitute is better than the real thing; he always knows, or pretends to know, better than the public what is good for it. Glucose, he says, is better than cane sugar for making jam; it keeps better and does not crystallise. Grain spirit is more wholesome, again, he urges, than malt spirit or grape spirit. But he can never be induced to state on the label the truth about the article. If the substitute is better, as he says, and the public persists in demanding it, why does he hesitate to describe his goods as such? The fact is, the public is badly deceived by the processes of substitution which are carried out on a very large scale in reference to a very great number of articles of food and drink. The country is sadly in need of a Bill to deal effectively with misleading labels and descriptions.

EPSOM COLLEGE: PRESENTATION TO DR. HOLMAN.

BEFORE the usual meeting of the council on August 5th the chairman, Sir Joseph Fayrer, presented to the treasurer, Dr. C. Holman, on behalf of the members, a testimonial in recognition of the great services which he has rendered to the institution for so many years, and especially as a mark of their appreciation of his efforts in connexion with the recent successful festival dinner held under the presidency of the Prince of Wales. The testimonial took the form of a large portrait, which is to hang in the council chamber of the College in Soho-square, and an illuminated address as follows:—

> "To Constantine Holman, M.D., Treasurer of the Royal Medical Benevolent College.
>
> We, your colleagues on the Council of the Royal Medical Benevolent College, desire to take the present opportunity, when we have just celebrated, under the presidency of His Royal Highness the Prince of Wales, the most successful festival dinner that the College has ever had, of expressing our sense of the great and valuable services [illegible] so many years, for 16 of which [illegible] easurer. [illegible] and work which have been so ungrudgingly given by you and to which the College so largely owes its present satisfactory position.
>
> We desire to offer our thanks for all that you have done and are doing, and to express our hope that you may long be spared to us and to the College.

The address was signed by the President of the institution and by all the members of the council and incorporated in the handsome illumination were sepia views of the College at Epsom. We are confident that Dr. Holman appreciated the simple and expressive terms in which his services to the College were referred to, and no more appropriate testimonial could have been selected than a portrait to be placed amongst those in the council room of the founder, presidents, vice-presidents, and other old friends and supporters of the institution. For 25 years Dr. Holman has watched over the College as a member of the council and for 16 years he has taken a most active interest in it as treasurer, while he has been a governor since the foundation of the institution 50 years ago. Truly he has merited every word in the address.

THE STORY OF COLOTOMY.

THE evolution of an operation is often of great interest. Occasionally an operative method springs full grown from the head of its inventor and subsequent years hardly witness any modification of it, but more frequently at its first appearance an operation is somewhat crude, and time and experience shape and mould it until in its maturity it is a very different procedure from what it was at its inception. Many surgeons improve the inventor's operation, modifying the idea first put forth, and tending to make the procedure easier and safer than it was before. Sometimes a useless or even a harmful change is suggested; it is taken up, tried for a time, and not fulfilling its original promise it is dropped. The operation of colotomy has undergone many and great changes since it was first thought of. In 1710 Littré suggested a left inguinal colotomy; in 1839 Amussat devised the lumbar operation and in pre-antiseptic days this was without doubt the better operation. As modified by various surgeons it became ultimately a fairly successful operation, for if skilfully performed it avoided opening the peritoneal cavity and yet afforded free exit to the fæces above the obstruction. Littré's operation, however, had never been completely abandoned and gradually during the last 20 years it has replaced Amussat's method, until at the present time the lumbar operation is hardly ever performed. Meanwhile, Littré's operation has been undergoing various modifications which have enhanced its value until it is now practically perfect. Mr. F. T. Paul of Liverpool, who has himself made some important improvements in the operation, took colotomy for the subject of a recent address which we print this week. His words show how success depends on attention to many small points. The discomfort due to the escape of fæces from which the patient formerly suffered no longer necessarily occurs, and if the operation has been performed for some non-malignant obstruction a man may lead a long and comfortable life even though he be the subject of a colotomy.

---

[1] THE LANCET, July 4th, 1903, p. 62.

THE FLY PLAGUE.

THE presence of flies in the house is a reproach. It is a falling away from a high hygienic standard, for the fly is a pestilential fellow. It must be admitted, however, that it is very difficult to keep habitable places free from flies. Poisonous fly-papers are unsightly and glutinous cords and traps are not very pleasant accessories in the household. Yet it is a matter not only of comfort but also of health that the fly should be excluded. The fly may easily be a pathogenic agent owing to the fact of its choice of environment being oftentimes of the most disgusting character. When a fly walks across a suitable culture medium it leaves infection behind it, as shown in the colonies of organisms which develop on the points with which the insect's legs have been in contact. The fly therefore should be driven out of our haunts. Preventive measures are best and at this season of the year, when flies are beginning to infest our houses, it is an excellent precaution to cover the window openings with wire gauze. It is a curious fact that flies will not pass through netting even though the meshes be quite large unless there be a source of light as from a window behind it. Thus in rooms with windows only on one side a net over the window will absolutely keep the flies out, although the meshes of the net may be an inch apart. It is surprising that in railway carriages a sliding frame fitted with wire gauze is not provided as well as the window. Such a sliding screen could be used when ventilation is wanted, while dust and rain would be excluded at the same time. The gauze frame would certainly keep flies out. We have seen carriages on certain of the continental lines provided with a gauze-screen of this kind. There is no reason why a similar arrangement should not be fitted to the ordinary window sash. This would do much to mitigate the great nuisance of flies in the house.

THE ROYAL COMMISSION ON LONDON TRAFFIC.

THE Royal Commission on London traffic, on the successful issue of whose recommendations the improved convenience of Londoners in their daily business largely depends, has recently taken steps that augur well for its efforts. The Commissioners have shown that they hold the worthy desire of seeing with their own eyes the things in judgment upon which they sit, and that they will not be content with mere reports and accumulated evidence. On July 31st, instead of sitting at the Westminster Palace Hotel to hear evidence, the Royal Commission took the practical and laudable step of personally inspecting the condition of the roads and of the congested neighbourhoods in and around the north-west and north-east districts of London. Six motor-cars were put at the disposal of the Commissioners by the members of the Automobile Club. The route taken was the Mall, Piccadilly, and so through Hammersmith-broadway to Hammersmith Bridge. A suggestion that seems to us of much value was made by Mr. Jeffreys, the honorary secretary of the Roads Improvement Association. This is to the effect that in order to relieve the pressure of traffic in Piccadilly it would be well instead of setting back the frontage to continue Pall Mall through Green Park so as to converge on Piccadilly at the widened portion near Hyde Park Corner. The value of such a road as an alternative route to Piccadilly would obviously be great. And there should be no great difficulty in carrying out such a suggestion, although the interference which would probably be necessary with part of the courtyard of St. James's Palace or with Warwick House and the little passage into the Green Park might be regrettable from the artistic and antiquarian point of view. Unfortunately, the practical demands of progress often bring about the demolition of the old, the graceful, and the comparatively extravagant to make way for the new, the useful, and the economical. Changes of some such nature are inevitable to procure more space for the traffic which at certain seasons of the year hopelessly blocks parts of Piccadilly.

IN connexion with the Royal visit to Ireland His Majesty the King has been pleased to confer honours upon various persons notable in their several stations. Among the names of more particular interest to the medical profession are that of the President of the Royal College of Physicians of Ireland, Dr. Arthur Vernon Macan, and that of the President of the Royal College of Surgeons in Ireland, Mr. Lambert Hepenstal Ormsby. Both of these gentlemen have received the honour of knighthood.

THE death at the age of 69 years is announced of Dr. John Tatham of Burton-in-Lonsdale, and late of George-street, Hanover-square. Dr. Tatham was for many years a member of the staff of the Hospital for Consumption and Diseases of the Chest, Brompton, and at the time of his death was consulting physician to that institution. The memory of his genial shrewdness with his patients and his powers of internal organisation will long be preserved there.

LORD IVEAGH has given to the King the sum of £50,000 to be divided among the Dublin hospitals of all denominations and the National Hospital for Consumption, Newcastle, county Wicklow. The gift is a worthy commemoration of the visit of the King and Queen to Ireland.

THE death is announced at the age of 84 years of Dr. Joseph Griffiths Swayne of Bristol, author of the famous Obstetric Aphorisms. In a future issue we hope to give a more extended notice of Dr. Swayne's career.

THE CANCER RESEARCH FUND: THE FIRST ANNUAL REPORT.

A MEETING of the general committee of the Cancer Research Fund was held on the afternoon of July 30th, at the offices of the Conjoint Board, Thames Embankment, London, W.C., the Right Hon. A. J. BALFOUR, Prime Minister, being in the chair. The first annual report of the Fund was presented and showed that the Cancer Research Fund had its origin in October, 1901, when a gentleman of considerable standing and pecuniary influence in the City stated to a well-known surgeon that he believed that he could raise in the City a sum of £100,000 or £150,000 for the carrying on of a systematic investigation into the cause of malignant disease. The Royal College of Physicians of London and the Royal College of Surgeons of England were approached by the surgeon, a member of the Council of the latter body, and as a result a general committee of the two Colleges was appointed to formulate a scheme of research. After a little unavoidable delay an appeal letter was published in the *Times* of April 18th, 1902, and leading articles were written in the columns of that paper and the medical journals advocating the scheme, which was understood from the beginning to have had Royal approval. A sum of £30,000 was quickly collected and a start was made in the investigation by the securing of a strong executive committee, the appointment of five trustees for the Fund, and the choice of Mr. Henry Morris as honorary treasurer and Mr. Frederic G. Hallett, secretary of the Conjoint Board, as secretary. Then a general superintendent, Dr. E. F. Bashford, was unanimously elected and given general control of the central laboratory of the Fund. Last autumn His Majesty the King was pleased to accord his patronage to the Fund and pathological and statistical subcommittees were appointed, while the laboratories of the Conjoint Board were placed at the disposal of Dr. Bashford by the Royal Colleges. The work of the Cancer Research Fund began immediately.

The report of the general superintendent, which, dating from November, 1902, may be said to cover little more than half a year's work, forms a clear statement of the steps which have been taken to organise a research upon as wide a basis as the funds available would allow. Extensive experimental work has not yet been undertaken, although progress has been made in studying varieties of malignant new growths in animals. Certain alleged therapeutic measures applied to cancer in man have been the object of serious attention and in particular the results of electro-therapeutics, the Finsen *light, high-frequency currents, and the x rays, have been carefully* examined, the medical men in charge of the electrical departments of hospitals having cordially cöoperated, while many medical men have made reports on the treatment of their cases. Work has also been directed to endeavour to establish the statistics of cancer on a secure pathological basis. An investigation and analysis have been undertaken of the records of deaths from malignant new growths in the London hospitals and the statistical committee after consideration of the results of preliminary investigation has recommended continuation of work upon these lines. Under Dr. J. F. W. Tatham's supervision certain clerks in the General Register Office are now engaged in abstracting from the registers of the last three years facts bearing on the relative incidence of fatal cancer on the more important occupations. A memorandum approved by the pathological and executive committees of the Cancer Research Fund has been printed by the Colonial Office as an official paper and issued by the Colonial Secretary to self-governing and Crown colonies along with covering despatches. The questions formulated in the memorandum are very definite ones and it is hoped that when they are answered the relations of the incidence of cancer to race and locality may be compared to some extent. An interesting financial statement by the honorary treasurer is added to the report, showing how carefully the work done has been proportional to the money received and pointing out how vitally necessary to the chances of success of the research a large increment of funds is. It was mentioned that contributions might be sent to the honorary treasurer, Cancer Research Fund, Examination Hall, Victoria Embankment, London, W.C., or to the account of the Fund, London and Westminster Bank, Marylebone Branch, Stratford-place, London, W.

Mr. BALFOUR then called upon Lord Strathcona to propose the adoption of the report.

Lord STRATHCONA, in moving the adoption of the report, directed attention to the lines laid down for work by the Fund, but said that it was too early to draw any deduction from the experimental researches, though important results were expected to follow the statistical information now being prepared on the same basis in the different parts of the world under the auspices of the Fund. There was one feature which was regrettable—namely, that the revenue derived from the Fund already subscribed was not sufficient to meet the expenditure which was necessarily being incurred, and in consequence it had been found necessary to draw upon the capital account. The fund so far subscribed was slightly under £50,000 and had been reduced by about £100 in the past year. It was most important that the amount should be made up to £100 000. Hitherto only 213 subscribers had contributed to the Fund. The report had been placed before the President of the Fund, the Prince of Wales, who had given his approval.

Mr. BALFOUR mentioned that if the Prince of Wales had been able to be present he would have taken an active part in suggesting that the report be adopted.

Mr. C W BELL seconded the motion which was carried.

Sir FREDERICK BRAMWELL moved a vote of thanks to the officers of the Fund and others who had assisted in its work during the year, and this having been seconded by Mr. HAROLD J. STILES, representing the Royal College of Surgeons of Edinburgh, was also carried.

Sir WILLIAM S. CHURCH, replying on behalf of the executive committee and the consultative staff, referred to the great difficulty which had been experienced in organising such an undertaking as that which they, the two Royal Colleges in London, were directing. At the outset two main points were considered to require immediate attention. In the first place it seemed to be essential to collect statistics in which attention had been paid not only to the diagnosis of the disease during life but also to post-mortem verification. In the second place, it was found extremely difficult to obtain a convenient locality—a few acres of land with suitable buildings, something of the nature of a small farm—for carrying on experimental work. Some of the lower animals were afflicted apparently with exactly the same forms of cancer as the human species and the object of the experimental work was to ascertain whether it was possible in them to establish a cancerous breed, whether the disease could be transmitted from parents to progeny.

Sir WILLIAM BROADBENT moved a vote of thanks to Mr. Balfour for presiding at the first annual meeting. In the course of his speech he referred to the interest which Mr. *Balfour had for some years taken in the subject and said* that in the medical profession more importance was attached to the prevention of the disease than to its cure. It was on these grounds that researches as to the pathological or etiological factors of the disease were felt to be so necessary.

Mr. JOHN TWEEDY seconded the motion which was carried.

Mr. BALFOUR, in the course of his reply, said that the results of modern medical and surgical treatment showed a [illegible] with what could be accomplished [illegible] 100 years ago and the progress [illegible] as rapid in the future as it had been in the past. With regard to cancer, isolated endeavour had now been going on in every hospital and by every medical practitioner in every civilised country of the world for years past. What was wanted was cöoperation between all the different workers in this field—not merely cöoperation among those engaged in combating to the best of their ability as practitioners the ravages of this disease but of those who, by their scientific and biological attainments, could throw some light upon the cause and *origin* of the disease. He noticed with much satisfaction that the scope of these researches would include the manifestations of the disease, not only in man but also in the lower animals. He believed that it would come as a surprise upon a large number even of the instructed public to know the degree to which not only mammals but even species lower in the scale of organisation suffered from a disease which in all its peculiarities seemed to be absolutely identical with that from which the human race suffered so greatly. It was probable that the wider sphere of fruitful study thus opened would contribute to the formation of some estimate of the cause and course of the disease, and some knowledge of the cause and course of the disease must after all be the basis of any reasonable attempt to find a mitigation or a cure. It was true that happy experiments, or the inspiration of some fortunate man of genius, might, in anticipation of these wider generalisations, suggest some effective remedy, but it was impossible to count upon this; and in any case the work of this fortunate genius could not fail to be aided by the generalisations to which the researches now being commenced must inevitably lead. He also sympathised with what was said by Sir William Broadbent to the effect that there was no supposed or suggested cure which the committee would regard as unworthy of investigation. The number of quack remedies, the number of perfectly futile remedies, which had from time to time been suggested, sometimes by those who were ignorant and sometimes by those who only desired to make money out of other people's ignorance, had been so great that none could wonder at the impatience with which the trained practitioner looked at most of the proposed cures; and it was to be feared that the vast majority of them would not bear any examination at all. But undoubtedly the proper spirit in which to enter into these investigations was not to reject hastily anything which has even a *primâ facie* claim to be considered. It was allowable to use hypothesis as a guide to the collection and examination of facts but not to start the collection and investigation of facts with any hypothesis so firmly rooted in the mind as to allow it to interfere with impartiality of the judgment. He was certain that this investigation had been, and was going to be, carried out with due attention to this precaution, and he earnestly advised the public not to show impatience at the slow march of discovery upon a matter which had defied the greatest physicians of the world up to the present time. He trusted that the public would go forward in a liberal spirit, recognising that success, however certain, must be slow; not to be too impatient of results nor too anxious to receive some equivalent in discovery for every subscription that they might give to the work. He hoped that they would be anxious to endow this great machinery for scientific and pathological investigation in a way which should, by the accumulated learning and experience of years, do something to mitigate one of the greatest curses under which humanity groaned. It was, however, disquieting to find that, though the sum which had been collected appeared to be a large one, it was nevertheless contributed by only 213 persons out of a community of 40,000,000. Considering that all of these 40,000,000 had either in their own persons or in the persons of those dear to them—wives, children, grandchildren—a direct interest in the successful result of these investigations, it was surprising that the contributors should be so few in number. He hoped that when the next annual meeting took place it would be found that others had come forward and that the result of their united efforts would be the providing of an assured financial basis which would be the best guarantee of ultimate success.

Sir William Church proposed that Sir Henry Howse should be added to the general committee as, in consequence of his having vacated the office of President of the Royal College of Surgeons of England, he necessarily went off the executive committee.

This was unanimously agreed to and the proceedings then terminated.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary Comitia was held on July 30th, Sir William S. Church, Bart., the President, being in the chair.

Seven gentlemen, having satisfied the Censors and given their faith to the College, were admitted Members. Licences were granted to 122 gentlemen who had satisfied the examiners and conformed to the regulations of the Conjoint Board. The Diploma in Public Health was awarded to 17 candidates on the recommendation of the examiners. George Francis Angelo Harris, M.D. Durh., elected on April 30th, was admitted to the Fellowship *in absentiâ* and the seal of the College was set to his diploma.

Communications were received from the secretary of the Royal College of Surgeons of England, reporting certain proceedings of its Council on July 9th; from the Worshipful Company of Spectacle Makers, asking the views of the College on a proposal that competency in sight-testing should in future form a subject of examination and certification for the diplomas granted by them to opticians (this was referred to the Censors for consideration and report); from the Dean of the Faculty of Medicine, University of Edinburgh, reporting the award of the Murchison scholarship, July, 1903, to Charles John Shaw, M.B. Edin.; and from Dr. Norman Moore, offering for the acceptance of the College an autotype portrait of Dr. Fitz-Patrick.

The election of Censors, other College officers, and examiners, on the nomination of the President and Council, was carried out.

A confidential report by the visitor and inspector of the General Medical Council on the Final Examination of the Conjoint Board was referred to the council of management for consideration and report.

A report was received and approved, dated July 22nd, from the conjoint committee appointed to consider and to report upon any alterations that may be desirable in the regulations for the First Conjoint Examination.

A report was received from the committee appointed to consider and to report on the question of the alleged physical degeneration of recruits for the army, the tenour of which was to the effect that the information furnished was not of such a character as to enable the College to express a decided opinion.

A report was received from the committee appointed to consider and to report on the practical safety and prophylactic value of anti-typhoid inoculation. This was to the effect that not only was a lessened susceptibility to the disease brought about as a result of the inoculation but that the case-mortality was largely reduced; also that with due care there was no direct danger, except possibly from some temporary increase of susceptibility immediately following inoculation.

A report was received from the representative of the College in the General Medical Council on the proceedings of that Council during its session in May last and at a special session in July.

The Parkes-Weber prize was awarded to Hugh Walsham, M.D. Cantab., F.R.C.P. Lond. The Council recommended that the Moxon medal should be awarded to John Hughlings Jackson, M.D. Aberd., F.R.S., as having especially distinguished himself by observation and research in clinical medicine. The Council also recommended that the Baly medal should be awarded to John Newport Langley, D.Sc., F.R.S., of Trinity College, Cambridge, as having pre-eminently distinguished himself in the science of physiology.

The quarterly report of the College finance committee was received and adopted, as were also the annual reports of the library committee and curators of the museum.

The quarterly report of the examiners for the Licence on the results of the April examination was received and also an application from Horatio George Adamson, M.D. Lond., praying for the restoration of Membership resigned by him in 1897.

The newly elected officers, examiners, and members of standing committees gave their faith to the College.

Looking Back.

FROM

THE LANCET, *SATURDAY*, AUGUST 6, 1825.

FOREIGN DEPARTMENT.

ANALYSIS OF FOREIGN MEDICAL JOURNALS.

On the insensibility of the Retina.

By M. Magendie.

It has already been shown, that some parts usually considered as nerves, and consequently as the organs possessed of the greatest sensibility, were, notwithstanding, impervious to tactile impressions; that they could be even pricked and lacerated without appearing to induce the least feeling of sensibility, and such were the olfactory and optic nerves of the retina.

About four months since a young woman was brought to M. Magendie, having two perfect cataracts, for the removal of which she expressed a very great desire, and the great wish M. M. had of ascertaining whether the retina did possess that exquisite sensibility so much insisted on by physiologists and metaphysicians, soon induced him to comply with her request. The cataract being of the soft kind could not be couched at once, it yielding to the pressure, and therefore only a portion could be depressed at a time; each time, however, a bit was carried down, the resistance from the parietes of the eye could be distinctly felt, forming at once a convincing proof of having pressed on the retina. Notwithstanding this, the patient not only did not complain, but appeared not even to have been conscious of such pressure being used, and which she necessarily must have shown had the retina been so sensible as is usually believed. Somewhat emboldened by this result, M. Magendie directed the needle towards the bottom of the eye and touched the retina very slightly; this was repeated five or six times, but the woman evinced no feeling of sensibility. It could not have happened that the retina was paralysed, for the instant the nervous membrane was touched she expressed her great delight on again seeing the light.

The other eye underwent the same treatment, the nature of the cataract being the same. This time, however, less caution was observed. The crystalline lens was depressed as completely as possible; the retina was freely touched in many parts with the point of the instrument, even with a force sufficient to have pierced through the membrane; all this, however, was done unknown to the patient, who felt no ill effects from it.

The experiment has subsequently been performed at the Hôpital de la Pitié, on a man affected with a cataract of the right eye. *The crystalline lens was easily depressed, and the sight immediately restored; at different times in the* course of the operation the retina was touched, but no sensation was produced indicative of any exquisite sensibility in the part.

In this case, as in the former one, the contact of the instrument, and even the pricks which were made in the retina, did not prevent the eyesight being completely restored. Thus it would appear, that the retina of man is devoid of sensibility except to the action of light, and thus far we in no wise differ from the lower animals.

"In a physiological point of view this result is more important, since," observes M. MAGENDIE, "it shows at all times the great superiority of experiments over abstract reasoning, and what deductions are more abstruse and complicated than those of philosophers, founded on the great sensibility of the retina!"—*Journal de Physiologie, June* 1825.

THE BATTLE OF THE CLUBS.

KIDDERMINSTER.

WE have received the following letter from the secretary of the Kidderminster Medical Society with a request for its publication:—

To the Editors of THE LANCET.

SIRS,—I write to inform you at the request of the Kidderminster Medical Society that after a conference with the Kidderminster Medical Aid Association the latter association has agreed to adopt the following new rules:—

1. A rule to prohibit canvassing.
2. That the cash reserve fund shall not exceed £300.
3. That it will not admit to the benefits of the association as public members any persons whose wages exceed £3 per week; also that the minimum contribution for public members of all ages shall in the future be *4d.* per month or *1s.* per quarter per member.

In consequence of this agreement the Kidderminster Medical Society has removed the professional disabilities previously imposed upon the medical officers of the Kidderminster Medical Aid Association and will in future meet them in professional consultation. I shall be obliged if you will publish this in your next issue.

I am, Sirs, yours truly,
O. O. PENRHYS EVANS,
August 1st. *Honorary Secretary, Kidderminster Medical Society.*

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on August 4th, Mr. JOHN TWEEDY, the President, being in the chair.

It was resolved that diplomas of Membership should be issued to 120 successful candidates.

As recommended by the Court of Examiners, the University of Birmingham was added to the list of Universities whose graduates may present themselves for the examinations for the Fellowship without first becoming Members of the College.

It was resolved that diplomas in public health should be issued jointly with the Royal College of Physicians of London to the 17 successful candidates.

It was resolved that, as recommended by the museum committee, facilities should be offered to the University of London for holding the examinations in pathology of the University at the College instead of at the Examination Hall, with the object of preventing the injury likely to be caused in course of time to the museum specimens by their frequent removal from the College premises.

It was resolved that the loan of museum specimens to the University of London for examination purposes be renewed for another year and that the University be requested to take into consideration the practicability of holding its examinasions in pathology at the College.

It was resolved that the loan of museum specimens to the Army Medical Department for examination purposes be renewed for another year.

Permission was granted, subject to the usual conditions, to Mr. George Pernet to make use of the dermatological *models, drawings, and specimens in the museum for the purpose of publication in the form of an atlas.*

It was resolved to have rooms Nos. 2 and 3 of the museum painted and therefore the museum will be closed from August 8th to Oct. 1st.

The balance-sheet was approved and adopted. It showed that the balance of income over expenditure amounted for the year to £2004.

The Council elected Mr. P. Sidney Spokes, M.R.C.S., L.D.S., a member of the Board of Examiners in Dental Surgery.

A report was read from the committee on the physical disability of recruits for the army which was appointed to consider a memorandum forwarded through the Home Office. The report was approved.

A letter was read from Mr. Thomas Bryant reporting the proceedings of the General Medical Council at its late session and the best thanks of the Council were given to Mr. Bryant for his services as the representative of the College.

A letter was read from Sir William Turner, K.C.B., President of the General Medical Council, forwarding copies of reports on the first examination under the Conjoint Board. The consideration of this was postponed until the October meeting.

A report from the conjoint committee on the first examination was received and entered on the minutes but its consideration was postponed until October.

A letter was read from Messrs. Davidson and Morris, of 40, Queen Victoria-street, solicitors to the Worshipful Company of Spectacle Makers, stating that the company had appointed a committee to consider two memorials signed by 220 opticians praying the company to include the subject of sight-testing in their examination and to extend their diploma by certification of efficiency therein and that the committee propose to sit in November next to hear evidence and will be glad to have the views of the College, more especially as to what further restrictions should be included in the agreement which is to be signed by the diploma holders in the event of the request of the memorialists being granted. The letter was referred to the President and the two Vice-Presidents to consider and to report to the October meeting.

A letter of thanks was read from Lieutenant-Colonel W. H. Cadge, I.M.S., thanking the Council for the resolution passed by it in reference to his uncle, the late Mr. William Cadge.

A letter was read from the Director of the Nottingham Museum and Art Gallery thanking the Council for the loan of the portrait of the late Sir Spencer Wells and stating that the portrait would be removed and returned by the museum agents and would be insured for such sum as the College may wish.

Mr. C. T. Dent and Mr. G. H. Makins were appointed trustees of the Hunterian and Jacksonian funds in place of Mr. Reginald Harrison and Mr. Alfred Willett, who had resigned on ceasing to be members of Council.

The Chairman of the Library Committee reported the presentation to the library by Professor Retzius of Stockholm of the following works: 30 tracts by Professor Retzius himself or in collaboration and 11 volumes of his own and his father's works, including "Anthropologia Suecica" and the "Anthropology of the Finns," and his edition of Johannes Muller's letters to Anders Retzius.

The b[illegible] re given to Professor Retzius [illegible]

The n[illegible] be held on Oct. 15th.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8853 births and 4153 deaths were registered during the week ending August 1st. The annual rate of mortality in those towns, which had been 13·7, 13·5, and 13·4 per 1000 in the three preceding weeks, rose to 14·4 per 1000 last week. In London the death-rate was 13·5 per 1000, while it averaged 14·8 in the 75 other large towns. The lowest death-rates in these towns were 3·3 in Hornsey, 5·4 in Leyton and in Handsworth, 6·5 in Plymouth, 6 6 in Bournemouth, 7 6 in Tottenham and in East Ham, 8·1 in Croydon, 8 2 in Kings Norton, and 8 3 in Reading; the highest rates were 19 9 in Tynemouth, 20 1 in Great Yarmouth, 20 2 in Birkenhead, 20 6 in Sunderland, 21·2 in Liverpool, 24·9 in Bottle, and 25 9 in Warrington. The 4158 deaths in these towns last week included 591 which were referred to the principal infectious diseases, against 441, 473, and 532 in the three preceding weeks; of these 591 deaths 330 resulted from diarrhœa, 84 from measles, 51 from diphtheria, 49 from whooping-cough, 43 from scarlet fever, 29 from "fever" (principally enteric), and five from small-pox. No death from any of these diseases was registered last week in East Ham, Hastings, Bournemouth, Burton-upon-Trent, West Bromwich, Derby, Huddersfield, and South Shields; the highest death-rates from the principal infectious diseases were recorded in Walsall, Aston Manor, Grimsby, Stockport, Bootle, Sheffield, Tynemouth, and Rhondda. The greatest proportional mortality from measles occurred in Ipswich, Wolverhampton, Coventry, Stockport, Sheffield, and Merthyr Tydvil; from scarlet fever in Great Yarmouth, Walsall, and in Bootle; from diphtheria in Reading and in Stockton-on-Tees; from whooping-cough in York; from "fever" in Grimsby and in Rotherham; and from diarrhœa in Aston Manor, Birkenhead, Bootle, Warrington, Tynemouth, and Rhondda. Small-pox caused two deaths in Leeds, one death in Liverpool, one in Bootle, and one in Gateshead, but not one in any other of the 76 large towns. The Metropolitan Asylums hospitals contained 66 small-pox patients on Saturday last, August 1st, against 77, 71, and 71 on the three preceding Saturdays; nine new cases were admitted during last week, against 31, seven, and 12 in the three preceding weeks. The number of scarlet fever patients under treatment in these hospitals and in the London Fever Hospital, which had been 1701, 1710, and 1711 at the end of the three preceding weeks, had further risen to 1726 at the end of last week; 237 new cases were admitted during the week, against 253, 243, and 229 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 127, 115, and 130 in the three preceding weeks, fell last week to 110, but were 18 below the number in the corresponding period of last year. The causes of 43, or 1·0 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Birmingham, Leicester, Nottingham, Salford, Bradford, Leeds, and in 49 other smaller towns; the largest proportions of uncertified deaths were registered in Bournemouth, Northampton, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·2, 15·2, and 15·4 in the three preceding weeks, fell to 14·7 per 1000 during the week ending August 1st and was 0 3 per 1000 above the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10 8 in Perth, 12 3 in Aberdeen, and 12:4 in Leith, to 15 4 in Edinburgh and 18·0 in Greenock. The 480 deaths in these towns included 28 which were referred to diarrhœa, 15 to whooping-cough, six to measles, five to diphtheria, five to "fever," three to scarlet fever, and one to small-pox. In all, 63 deaths resulted from these principal infectious diseases last week, against 82, 57, and 62 in the three preceding weeks. These 63 deaths were equal to an annual rate of 2 0 per 1000, which was 0 4 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 31, 22, and 34 in the three preceding weeks, fell last week to 28, of which 15 occurred in Glasgow, four in Dundee, three in Edinburgh, three in Aberdeen, and three in Paisley. The deaths from whooping-cough, which had been 18, 15, and 11 in the three preceding weeks, rose again last week to 15 and included eight in Glasgow. The fatal cases of measles, which had been 13, 11, and seven in the three preceding weeks, further decreased last week to six, of which three were registered in Edinburgh and two in Glasgow. Of the five fatal cases of diphtheria four occurred in Glasgow. The deaths referred to different forms of "fever," which had been nine, three, and six in the three preceding weeks, were five last week and included three in Glasgow. The deaths referred to diseases of the respiratory organs, which had been 90, 73, and 79 in the three preceding weeks, fell to 68 last week, but were 11 below the number in the corresponding period of last year. The causes of four, or 0·8 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·2, 16·0, and 17·5 per 1000 in the three preceding weeks, rose again to 18·3 per 1000 during the week ending August 1st. During the past four weeks the death-rate has averaged 17 5 per 1000, the rates during the same period being 13 1 in London and 14 6 in Edinburgh. The 133 deaths of persons belonging to Dublin registered during the week under notice showed an excess of six over the number in the preceding week and included five which were referred to the principal infectious diseases, against two, six, and nine in the three preceding weeks; of these, four resulted from diarrhœa and one from measles. These five deaths were equal to an annual rate of 0·7 per 1000, the death-rates from the principal infectious diseases last week being 1·6 in London and 1·4 in Edinburgh. The 127 deaths in Dublin last week included 40 of children under one year of age and 20 of persons aged 60 years and upwards; the deaths of infants showed an excess of 27, and those of elderly persons a decrease of 17, as compared with the respective numbers recorded in the preceding week. Six inquest cases and six deaths from violence were registered and 49, or more than a third, of the deaths occurred in public institutions. The causes of seven, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Surgeon A. R. Bankart, M.V.O., of the royal yacht *Victoria and Albert*, is specially promoted to Staff Surgeon for distinguished service.

The following appointment is notified:—Staff Surgeon R. Hill to the *Racer* for Osborne College, cadet sick quarters.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors (dated July 28th, 1903):—F. J. W. Porter, D.S.O., O. L. Robinson, C. E. G. Stalkartt, T. W. Gibbard, C. J. Healy, H. J. M. Buist, D.S.O, G. B. Stanistreet, F. J. Wade-Brown, W. E. Hardy, J. E. Brogden, G. W. Tate, N. Faichnie, T. J. Lenehan, F. McDowell, F. W. Begbie, I. A. O. MacCarthy, C. W. Duggan, and J. C. Jameson.

Lieutenant F. C. Lambert, from the Seconded List, to be Lieutenant. Dated August 1st, 1903.

The undermentioned Lieutenants are confirmed in that rank:—J. G. Bell, M. G. Winder, J. Gatt, T. S. Coates, A. E. B. Wood, J. C. G. Carmichael, R. H. Bridges, J. A. W. Webster, J. B. Meldon, R. C. Wilmot, C. W. Holden, H. B. Kelly, E. M. Pennefather, G. H. J. Brown, B. H. V. Dunbar, D. Ahern, and D. G. Carmichael.

Captain A. Cuddon Fletcher has arrived in the Home District for duty and Captain W. J. Taylor joins the Home District for duty on Sept 1st. Captain F. Kiddle is ordered to the Western District for duty.

The undermentioned officer of the 3rd Battalion Australian Commonwealth Horse is granted temporary rank in the Army whilst serving in South Africa:—To be Captain (dated April 2nd, 1902): Captain Alexander Fullerton, medical officer.

The undermentioned officer of the 4th Battalion Australian Commonwealth Horse is granted temporary rank in the Army whilst serving in South Africa:—To be Captain (dated March 26th, 1902): Captain Adam Richard Stacpoole, medical officer.

The undermentioned officer of the 5th Battalion Australian Commonwealth Horse is granted temporary rank in the Army whilst serving in South Africa (dated May 22nd, 1902):—To be Lieutenant: Lieutenant George Lawaluk *Bell*, medical officer.

The undermentioned officer of the 6th Battalion Australian

Commonwealth Horse is granted temporary rank in the Army whilst serving in South Africa (dated May 19th, 1902) :—To be Captain: Captain Douglas Andrew Shields, medical officer.

The undermentioned officer of the 7th Battalion Australian Commonwealth Horse is granted temporary rank in the Army whilst serving in South Africa (dated May 19th, 1902) :—To be Lieutenant: Lieutenant George Alexander Webster, medical officer.

The undermentioned officers of the Field Hospital and Bearer Company of the Australian Commonwealth Horse are granted temporary rank in the Army whilst serving in South Africa, as follows (dated Feb. 12th, 1902) :—To be Majors: Major Terence Albert Green, D.S.O., and Major Neville Howse, V.C. To be Captains: Captain Frederick David Jermyn and Captain Arthur John Nyulasy. To be Lieutenants: Lieutenant William Arthur James, Lieutenant Henry H. Formby, and Lieutenant David Duncan Cade.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major James Mackay having resigned his appointment in the Volunteers, ceases to be an officer in the Army Medical Reserve of Officers. Surgeon-Captain W. J. Lawrie, having resigned his appointment in the Volunteers, ceases to be an officer in the Army Medical Reserve of Officers.

ROYAL ARMY MEDICAL CORPS (MILITIA).

The undermentioned Supernumerary Officers are absorbed into the Establishment: Captain T. W. G. Kelly (dated August 1st, 1903); Captain H. E. Mortis (dated August 1st, 1903): Captain J. E. O'Connor (dated August 1st, 1903); Lieutenant M. A. Cholmeley (dated August 1st, 1903); and Lieutenant H. Fox (dated August 1st, 1903).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 4th Durham: Surgeon-Lieutenant W. Gray to be Surgeon-Captain. Dated July 11th, 1903. 1s [illegible] W. Chalmers-Cowan to be [illegible])ated July 18th, 1903. 1st [illegible] Surgeon-Lieutenant W. Hind to be Surgeon-Captain. Dated August 1st, 1903.

Royal Engineers (Volunteers): 1st Bedfordshire: Surgeon-Lieutenant A. O. Hartley to be Surgeon-Captain. Dated August 1st, 1903.

Rifle: 1st Volunteer Battalion the Northumberland Fusiliers: Surgeon-Captain W. B. Mackay to be Surgeon-Major. Dated August 1st, 1903. 1st Volunteer Battalion the Royal Sussex Regiment: Harold Vaughan Pryce to be Surgeon-Lieutenant. Dated August 1st, 1903. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment: Second Lieutenant R. D. Evans resigns his commission and is appointed Surgeon-Lieutenant. Dated August 1st, 1903. 6th (Fifeshire) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Lieutenant J. S. Mackay to be Surgeon-Captain. Dated August 1st, 1903. 3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Captain J. Strang to be Surgeon-Major. Dated August 1st, 1903.

FEES FOR CIVILIAN MEDICAL PRACTITIONERS.

By a recent Royal Warrant it is provided that when a detachment of the army is not within reach of a military medical man, the officer commanding may call in a civilian medical man to render medical attendance to the officers and men belonging to the detachment, and to other persons entitled thereto at the public expense, at the undermentioned yearly rates (which includes the cost of medicines) :—If there are less than ten persons, £5; if there are ten persons or more, for every complete 25, or a portion of 25, provided that the total emoluments for all services, exclusive of the examination of recruits, shall not in any instance exceed £1 for any one day, £10. In special circumstances, and when the medical duties required of the civilian practitioner do not come within the range of ordinary medical attendance, the remuneration shall be at such rates as may be determined by the commander of the army corps or the officer commanding a district lying outside an army corps command.

MENTIONED IN DESPATCHES.

In despatches relating to the Kano-Sokoto Campaign, published in the *London Gazette* of July 31st, Mr. W. H. Langley, L.R.C.P., L.R.C.S. Irel., principal medical officer, is mentioned as having worked hard and well throughout the operations.

NEW ROYAL ARMY MEDICAL CORPS UNIT.

A new unit of the Royal Army Medical Corps to be designated No. 20 Company was formed at Salisbury Plain on August 1st, under the command of Major C. E. Faunce, R.A.M.C. All officers, warrant officers, non-commissioned officers, and men of the Royal Army Medical Corps at present serving on Salisbury Plain, with the exception of those temporarily employed, will be taken on the strength of the new company.

Correspondence.

"Audi alteram partem."

PHIMOSIS AND CANCER OF THE PENIS.

To the Editors of THE LANCET.

SIRS,—As some emphatic statements have lately been published to the effect that phimosis is a potent cause of cancer of the penis[1] which I believe convey an erroneous impression, I shall be obliged if you will allow me brief space to justify my contention. An elongated, tight, phimotic condition of the prepuce is one of the very commonest anomalies and a large proportion of the male population is attacked in this way, often to an extreme degree. If therefore phimosis be, as alleged, a potent cause of cancer of the penis this particular local variety of cancer should be very common. The fact is, however, that cancer of the penis is one of the rarest forms of malignant disease—less than 4 per cent. of all cancers in men being of this variety.[2] If phimosis were really a potent cause of cancer of the penis how very different would this proportion be. According to American observers the negroes of that country are almost universally affected with phimosis, yet among these people cancer of the penis is of even rarer occurrence than in England; thus Rodman of Philadelphia has never seen a case in the practice of a lifetime and the Philadelphia hospital registers for a period of 30 years do not record a single case, although other forms of cancer are common. The experience at Louisville is similar, for out of 207 deaths from cancer in negroes not a single one was due to cancer of the penis.

I am, Sirs, yours faithfully,

Clifton, Bristol, July 30th, 1903. W. ROGER WILLIAMS.

THE USES OF PILOCARPINE.

To the Editors of THE LANCET.

SIRS,—The use of pilocarpine in pneumonia, mentioned by Mr. William Roper in THE LANCET of August 1st, p. 342, was first brought to notice by Sziklai some years ago. By him it was regarded as a specific for that disease, but many observers have doubted this—notably, Rosenberg who holds that pilocarpine, even when given in physiological doses, aggravates the symptoms of pneumonia. I have notes of 15 cases where treatment was commenced with pilocarpine nitrate alone, given hypodermically in doses of one-tenth to one-fifth of a grain twice in the 24 hours. They were all adult hospital cases in the early stages of pneumonia. In one case, that of a man apparently in good condition, after the second dose severe dyspnœa suddenly came on, followed rapidly by collapse and heart failure. In spite of atropine and cardiac stimulants the man never rallied. In another strangury with retention of urine, severe vomiting, diarrhœa, and heart failure occurred after three doses, but in this case the patient eventually made a protracted recovery. In three others the gastric irritation produced nausea and vomiting which was so marked that the further use of the drug had to be discontinued. The rest made uneventful recoveries. Afterwards I tried several cases with pilocarpine in conjunction with strychnine with good and satisfactory results. With the exception of the two cases mentioned I have not met with any heart failure; this I attribute to the action of the free sweating in lowering the temperature of the body and at the same time ridding it of some noxious products of tissue waste. I am certain also that in some of the cases the pilocarpine has had a good effect on the enfeebled digestive powers. At the same time I am satisfied that all these effects can be obtained by the use of other and much safer drugs.

---

[1] Polyclinic, May, 1903.

[2] Of 2669 men with cancer under treatment in London hospitals I have found that only 106 had cancer of the penis, and of 2831 similar cases in Vienna hospitals Gurlt found only 108 thus affected.

I am, Sirs, yours faithfully,
August 3rd, 1903. J. F. HODGSON, M.D., Ch.B. Vict.

To the Editors of THE LANCET.

SIRS,—The letter of Mr. W. Roper in THE LANCET of August 1st (p. 342) suggests a few further remarks from me on the dose and action of pilocarpine in the treatment of pneumonia. One of the chief uses of the drug in this disease seems to consist in the relief of pleuritic pain by liquefying "dry" pleuritic exudation, thereby permitting a freer inspiratory excursion and relieving negative pressure on the heart, the unembarrassed action of which it is so desirable to try to maintain. The second most important action is secretory and that this is an active process of the epithelial cells and not dependent on filtration is, I think, sufficiently demonstrated, apart from the well-known experiment on the parotid gland, by the almost constant initial rise of temperature of from ½° to 1½° F. after its administration. In this way the toxin of pneumonia, which is probably intracellular, is evicted.

The dose of one-third of a grain, as suggested by Mr. Roper, is by no means free from danger, as in addition to the depressing effects of purging and vomiting which it often produces the bronchial secretion may be so profuse as to cause alarming symptoms of asphyxia in debilitated subjects and more especially in those in whom toxæmic symptoms are a marked feature. Such patients often only half expectorate and in the deep inspirations following a severe attack of coughing a quantity of fluid mucus may be sucked into the infundibula of the sound portions of both lungs, resulting in serious consequences.

Until further clinical experience of this powerful drug is obtainable I do not consider it safe or prudent to give more than one-tenth of a grain hypodermically, at all events in pneumonia. This dose I employed in South Africa in 1901, and from a subsequent experience of over 30 cases in Kaffirs and whites, chiefly the former, I have no reason to use a larger quantity. One-third of a grain may have its uses in other diseases but all that is required in pneumonia is accomplished by the smaller dose which may be repeated on the following day if necessary.

I am, Sirs, yours faithfully,
Bournemouth, August 3rd, 1903. E. CURTIN, M.D. R.U.I.

CONTINUOUS RECTAL ALIMENTATION.

To the Editors of THE LANCET.

SIRS,—Information kindly supplied by Dr. H. D. Rolleston enables me to state that a method almost identical with that which I recently demonstrated at the Swansea meeting of the British Medical Association had been described in 1886 by Dr. D. J. Mackenzie of Glossop.[1] The chief point of difference is in the mode of regulating the rate of delivery. Dr. Mackenzie, using a tube of small diameter, varies the level of the vessel containing the fluid for injection. The screw-clip which I have employed is, perhaps, a simpler way of controlling the outflow. The apparatus is also simplified by immersing part of the length of the tube in a basin of hot water as this obviates the necessity for applying a constant supply of heat to the container. Other modifications of the same method may have been put into practice references to which would be much valued.

I am, Sirs, yours faithfully,
Curzon-street, W., August 4th, 1903. WM. EWART.

THE TREATMENT OF GOITRE BY DISTILLED OR RAIN WATER.

To the Editors of THE LANCET.

SIRS,—Kindly allow me to make some further remarks on this subject, especially as some of your correspondents appear to have a little misunderstood my previous letter, though it is encouraging to find that the general opinion is in favour of my views and that so many have had favourable experience in the same direction. Of course, I attribute no *positive* therapeutic influence to distilled or rain water; no "*specific*" influence, that is to say. The influence is *negative* and lies simply in its eminent purity and freedom from possible sources of contamination, as I think my letter sufficiently makes manifest.

No doubt, for many years past, the occasional connexion of the development of goitre with drinking water of an imperfect purity ("bad" water) and especially with "hard" water—i.e., water containing lime or earthy salts in solution —has been observed or suspected, and a change of drinking supply recommended. Instances might be multiplied of this. Some years ago, I am informed, quite an epidemic of goitre prevailed at Ackworth School in Yorkshire. The water-supply was changed and it disappeared. I have myself recommended for years that in such cases some pure soft water or rain water should be substituted with advantage.

The important point, however, is that in the cases I gave the water-supply is quite unexceptionable. The waters supplied by the Lancaster and Fylde Companies are both regarded by experts as beyond cavil both as regards purity and hardness. They are pre-eminently pure and soft waters. And yet they must contain an influence deleterious to the thyroid gland, else why the rapid change when distilled or rain water (in other words, distilled water, artificial or natural) was substituted? What is this influence or element in the water—this "goitrous poison," as Dr. Stevenson truly terms it? It remains unknown and undiscovered. It was at one time supposed to be lime but that has been disproved; indeed, the present cases would dispose of such a theory. In the cases I described it was the known purity of the water that lulled suspicion in my mind for some time and this no doubt also misled the authorities in London and Germany to whom I alluded. I find no reference in any text-book I have consulted to the use of distilled or rain water in such cases. The goitre is regarded as due to other causes.

Your correspondent, Dr. Stevenson, in his letter in your issue of August 1st, p. 340, speaks of the absence of goitre in Constantinople and Venice where rain water alone is drunk. I have also a letter from a medical correspondent who tells me that in a tract of Queensland containing a population of 20,000, where the people drink rain water only, a resident there for seven and a half years has never heard of a case. If these be proved facts, and I have no reason to doubt them, they furnish highly important factors in a knowledge of the causation of the disease and go far to prove that *water and water alone* (or rather that with which water has been accidentally associated in its course over and through the earth) *is responsible for goitre.* I am therefore justified in insisting that there are deleterious matters, beyond the reach of the analyst to determine, by which water may, and often does, become affected in its course towards collection and distribution in the usual way. The "goitrous poison" is evidently not acquired in the air, or rain water would manifest it; it must therefore be acquired in the earth.

That the poison attacks usually a few susceptible individuals only is but another illustration of the parable of the "sower and the soil," and when the conditions are very favourable to the development of thyroid mischief (when the susceptibility is great) it is not to be wondered at that the effect will remain even after the cause has been removed, and that the goitre persist though perfectly pure water be consumed hereafter.

I am, Sirs, yours faithfully,
Lancaster, August 3rd, 1903. C. A. RAYNE, M.D. Lond., &c.

APPENDICITIS—A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In your report of the Medicine Section of the British Medical Association meeting at Swansea, the impression of what I said is a little misleading. I stated that in subacute appendicitis, particularly as occurring in elderly people, an aperient with belladonna in physiological doses and assisted by hot fomentations, &c., was often useful. I went on to say that in the acute forms where the onset was not so extremely severe as to require immediate operation, large doses of the tinctures of opium and belladonna in their usual relative proportion (three to one), given frequently until, and except when, the patient was asleep, and continued, with water only also permitted, for several days gave me good results. The water, until the vomiting had ceased, was given in teaspoonful doses every quarter of an hour.

---

[1] Cf. Brit. Med. Jour., June 19th, 1886, vol. i., p. 1161.

I might add that in two cases in which I had sought the coöperation of a surgeon, but in which it was decided not to operate, *the inflammation was so severe that in the one at an* operation undertaken 18 months later the appendix was represented only by adhesions and caseous débris was found along the pelvic border up to and even beyond the pubes. In the other, a hospital case, a subphrenic abscess developed and burst through the lung, the patient's life being only saved by large doses of brandy and strychnine hypodermically every half-hour at first; both of these patients are now in excellent health. I trust that you will be able to find room for this addition to your report. With thanks in anticipation, I am, Sirs, yours faithfully,

Chester, August 3rd, 1903. HENRY W. KING, M.D. Edin.

GRANADA: ITS HIGH DEATH-RATE AND CONTAMINATED WATER-SUPPLY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

AFTER an absence of many years, finding myself in Madrid for the International Congress, I returned to Granada anxious to see what improvements had been effected in that most picturesque but deplorably unhealthy town. After spending six hours in the train to accomplish a journey of 77 miles from Bobadilla junction I arrived at this ancient Moorish capital and it became at once apparent that there had been some attempt at haussmannisation. A new boulevard has been cut right through the centre of the *town, letting light and air into some dark and unwholesome places.* It was the Chamber of Commerce that took the initiative in piercing through one of the worst quarters so as to create a new and broad street. It managed to buy up nearly all the houses by means of friendly negotiations. The poorer sections of the population who were thus forced to quit their tenements went to live in the Albaicin quarter, where many empty houses may be found, though in the days of the Moors this part of Granada was thickly populated. Beyond the cutting of this new thoroughfare and the creation of an institution for the provision of lymph from the calf, little or nothing seems to have been attempted to improve the sanitation of the town. There has been a good deal of talk about the most urgent of all needed reforms, the water-supply, but nothing has been done. Yet it would be impossible to find any place where the necessity of protecting the water-supply has been more frequently and emphatically indicated. Countless thousands of human beings have been poisoned and brought prematurely to the grave by the water drunk at Granada. This fact is proved most conclusively by the statistics, by the high death-rate, and by appalling epidemics, yet year after year rolls by and nothing is done. Once more, therefore, the ghastly story must be repeated, and if the fear of death and the desire to save life and to reduce the sum-total of human suffering do not suffice to make the inhabitants of Granada take action then perhaps they may be awakened by a sense of shame when they find themselves publicly denounced. Public contumely if nothing else may induce them to endeavour to remove so disgraceful a stain on their local and national reputation. Good work has been done in Spain. In spite of poverty and political troubles various improvements have been effected at Madrid and elsewhere, but nowhere was there greater need of such measures than at Granada; no town has suffered so much; nowhere is the danger more evident.

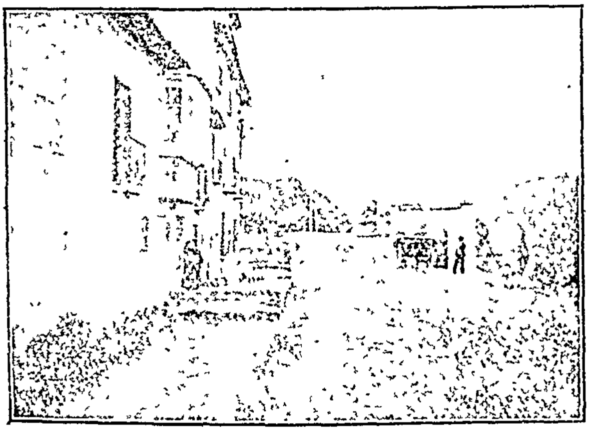
To render this clear to those who are unacquainted with the local history of Granada some words as to the past are necessary. Thus, according to official figures, the rate of mortality in Granada during the ten years 1860 to 1870 inclusive was equal to 40 4 per 1000 per annum. During the next decade there was no material improvement, and then in the following decade came the punishment, the appalling cholera epidemic of 1885. It will be remembered that the deaths were then so numerous that it was impossible to bury the victims of the cholera and hundreds of bodies without coffins lay rotting in the open air. The stench was blown over to the suburb of Zubia, and the epidemic spread to that district, killing among others the Archbishop of Granada. It was by the employment of criminals, who were beaten with sticks, urged forward at the point of the bayonet, and threatened by loaded rifles, that Lieutenant Varona saved the situation and finally had the accumulation of bodies *buried at the rate of 500 per day. What all this meant may* best be understood when the fact is recalled that there were 313 deaths from cholera in one single day out of a population of 75,000. This would mean, if calculated at the same proportion, more than 20,000 deaths in Greater London from cholera alone, and this in one single day. Perhaps in such circumstances difficulties might arise in London as in Granada, for it would be no easy matter to bury so large a number of cholera-stricken people. It is not necessary, however, to enter into further details concerning this hideous epidemic. It caused a profound sensation at the time not only in Spain but throughout the world and efforts were made to send help to the sufferers. A special fund for that purpose was opened at the Mansion House in London and met with a generous response. But while help thus came from afar who would have imagined that those on the spot and who had been, and in the *future will be, the first to suffer would do nothing* for themselves? The official statistics published before the outbreak of the cholera epidemic in 1885 showed that about one-third of the deaths occurring in normal times at Granada were due to intestinal disorders. This very high proportion is ascribed to the pollution of the water-supply. Nobody challenges this opinion and yet nothing is done. *The terrible cholera epidemic of 1885* would, it was thought, bring about the long-needed reforms; nevertheless there is no change. The death-rate has been slightly reduced, probably as a result of the new boulevard and the abolition of some slums, but it is still equal to 38 per 1000 per annum. The deaths due to intestinal disorders are equal to 25 per cent. of the total deaths, whereas taking Spain as a whole they only amount to 14 per cent. Therefore the conditions that produce this form of disease are exceptionally prevalent at Granada.

These fatal conditions are well known. They have been denounced over and over again and there is absolutely no excuse for their continued existence. Granada is most favourably situated. Everything except the ignorance and apathy of its inhabitants combines to make it what it was in the days when the Moors brought their science and civilisation to Europe. There is an exceptionally ample supply of pure water coming from the neighbouring hills, the offshoots of the Sierra Nevada, but so careless are the inhabitants that this water is rendered most foul before it reaches the houses where it is used for drinking purposes. Again, the topographical position of the town is such that there are exceptional facilities for drainage and beyond there are vast plains where the sewage could be utilised for irrigation purposes and the processes of purification would thus render service to local agriculture It was in the year 711 that the Moors under Tarik defeated and killed the last Visigoth king and soon after they began to build and notably at Granada. It was not till the year 1492 that this town was recaptured by the Spaniards. Now the Moors at once introduced a system of drainage and of water-supply and, for that distant period, what they did may well be qualified as advanced sanitary engineering. The Moors built sewers and instituted water-carriage drainage and sewage farms many centuries before anything of the sort was attempted in Christian Europe. When the Christians got back to Granada they did not know how to utilise the sanitary works which the Moors had left behind Instead of attending to the sewers, repairing and rebuilding them, they were left to decay and their contents were allowed to escape into the subsoil. This is all the more dangerous as the water-supply is delivered in small earthenware pipes of the same manufacture as that which existed in the times of the Moors and this would not now be qualified as sanitary material. It is not enamelled inside; it is light, brittle, and porous. The streets are so narrow that these conduits must be laid close to the sewer. If they sometimes escape contamination from the leaking sewers it is because they are laid on a level with the top rather than the bottom of the sewers. In this latter case, however, they are so near the paving-stones that they are frequently contaminated by the dirt of the street. Sometimes these pipes are broken by the passage of a heavy cart or some sudden shock, and then the water comes bubbling up into the street, causing a pool, a mess, a little rivulet, and an accumulation of mud which will remain for several days or weeks before the pipe is mended. One of the dangers of a large almost inexhaustible water-supply is that when a pipe bursts or leaks there is no urgent necessity to prevent waste and therefore accidents that lead to the contamination of the supply remain unrepaired for an indefinite time.

Instead of using bent or elbow-shaped pipes there are junctions formed in various parts of the street. These are primitive and clumsy contrivances and simply consist of little pits where pipes coming from different directions meet. As the pit fills the water runs down the different pipes and thus it is made to turn the corners and to flow from the street at right angles into the houses on either side. Over these little distributing catch pits, if they may be so described, a flagstone is placed and a circular aperture about five inches in diameter is cut out of this stone. A stone of about the same size is jammed in. Sometimes this gets loose and is kicked away and there is a hole through which the drinking water may be seen from the street causeway, through which also the dirt from the street, from the boots of the people passing by, falls without let or hindrance into the water which the people drink. Such a hole I noticed opposite the door of a medical practitioner's residence and close to the Ayuntamiento, yet neither the frequenters of the town hall nor the practitioner would seem to have taken the slightest trouble to remedy this evident cause of contamination of water. That poverty-stricken people who do not know how to read or to write should not notice these things can be understood; but here we have members of the municipality, members of the medical profession, and others who should know better, walking daily by places where the water-supply is contaminated, accidentally kicking the dust off their own boots into the water, and yet they do not seem to make the slightest effort to save themselves and the rest of the population from this great danger. Such apathy is truly extraordinary.

Nor is it within the walls of the town and in its streets only that the water is contaminated. Outside the water arrives in open channels. During the great cholera epidemic of 1885 it was pointed out that a lady who contracted the disease and died after only eight hours' illness had a "vista" window to her room which was actually suspended over the uncovered stream of the Granada water-supply. Nearly 18 years have elapsed since this occurred. The population on the banks of the stream has increased. Nothing whatever has been done to protect the supply and I was able to photograph the house with its projecting or "vista" window still hanging over the water-supply. (See Fig. 1.) There is, indeed, an entire terrace of houses overlooking the water and on the other side of the stream there is a high-road which also contributes its supply of dust and dirt to the water. Coming still nearer to the town the stream and the road pass by a high wall bounding and upholding a terraced garden. It was raining when I visited this place and I was able to take a photograph which showed the drainage from the garden, mixed, of course, with whatever manure may be used in the garden, flowing from water-spouts right into the stream. (See Fig. 2.) It will be noticed that at the point where I took the photograph the stream leaves the base of the wall, passes under the high road, and comes out on the other side of that thoroughfare. Not a thought seems to be given to the many chances of contamination that so evidently exist. A roughly constructed bridge spans the stream, the sides of the roadway crumble into the water, and the drainage from a manured garden or the dust and dirt of a terrace of houses all fall into the water without let or hindrance. At last, when close to the town by the Puerta de los Molinos, the stream is roughly roofed over with flagstones that fit very loosely. Here there is a cluster of houses and cottages built right over the stream. In the small backyard of one of these houses, where there was a stable with manure on the ground, the flagstones covering the stream were bare and through the interstices I could see the water passing underneath. After thus collecting some of the liquid stable manure from the back of this cottage the stream goes under an open space between houses. Here there is a rough track leading up a hillside and down the centre of this road there is a very small rivulet or gutter. Now the inhabitants of the surrounding houses, without thought of the water-supply passing below, have piled up some big loose stones so as to create a small dam and though there is not much water coming down the side of the hill at this point, still it suffices with the aid of the stones to form a few little puddles where the women can wash the dirty linen. Between these puddles and the water-supply flowing beneath them there are only a few inches of earth and locse-fitting flagstones. The

FIG. 1.



Photograph taken in June, 1903, of houses where cholera was found in 1885. The "vista" window of the room where a fatal case occurred, still projects over the unprotected water-supply.

FIG. 2.

High wall bounding a terraced garden which is drained by water-spouts into the open water-supply.

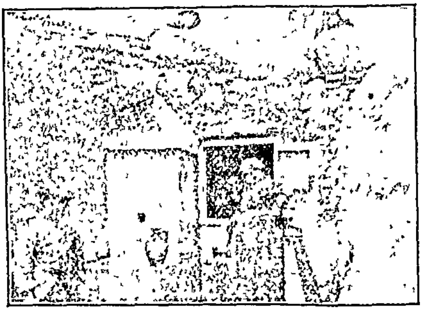
FIG. 3.

Women washing dirty linen at a surface stream beneath which, and in communication with which, flows the water-supply.

water soiled by the dirty linen must therefore to some extent fall into the drinking supply. The women who were washing when I took the photograph were kneeling immediately upon the roof of the channel or aqueduct which passes underneath and conveys to Granada a very large portion of the water drunk in that town. (See Fig. 3.)

There are three main sources feeding different parts of the town, the acequia Gorda, the acequia Cadi, and the acequia de San Juan, and I have described that which follows the Camino de Guiejar and supplies the most important part of the town. Of the other two sources one supplies the Alhambra Hill and the other the Albaicin Hill and quarter. In regard to the latter I also took a photograph on the side of the hill, not far from the church of San Juan. The canal here is by the side of one road and under another road that is on a higher level. A door has been cut into the side of the aqueduct and people come and dip their pitchers into the water, taking what they need for domestic purposes. Of course, the outsides of these jugs and pitchers are more or less soiled and yet they are dipped into the water. To prevent this obvious cause of contamination the doors during the time of cholera were locked and a pump was built by the side of them so that water could be pumped out. But this was found to be a slower process than dipping the pails and jugs into the water, so the locks and pumps were destroyed and the simple, quick but dangerous process was renewed. The photograph I have taken shows that a road passes by the side of the water canal, another road above, that the door giving access to the water is open, that a woman is about to dip a bucket into the water, and that the pump which was to prevent this form of contamination has been broken. (See Fig. 4.) Many other such means of direct ingress to the water-supply exist along the whole route.

FIG. 4.



Woman about to dip her arm and jug, both presumably dirty, into the water-supply, the pump being broken.

The water thus carelessly brought to the town is not filtered but delivered just as it is to the inhabitants. It is not often drunk just as it arrives. Not so much for the purpose of purifying as for the sake of obtaining cool water, great earthenware jars, some six feet deep and from two to three feet wide, are sunk in the soil below and underneath the houses. Then when the flow of water from the pottery pipes in the streets seems clear and free from dirt bucketfuls are drawn off and poured into these jars—jars of the same type as those in which Ali-Baba hid his 40 thieves. Here the water remains and is perhaps not touched for weeks. The object in view is to have cool water; the necessity of possessing pure water is not yet understood in spite of the lessons which cholera and the high death-rate should teach. Nothing can be more discouraging than to see that so little progress has been accomplished, though the need of a few elementary measures of sanitation is so very obvious. The statistics show that the death-rate of Granada is just about double what it should be, and this in the circumstances is not surprising. Such a high death-rate must give a corresponding sick rate. If the people of Granada are indifferent to the immense amount of human suffering which this entails, and which could easily be prevented, then they might at least think of the cost, the loss in money that these unhealthy conditions cause. They are always complaining of their poverty and certainly a very large proportion of the inhabitants of Granada are professional beggars and nothing else, but with better health better work could be done, and also many more tourists and visitors would bring wealth to the town. As it is, travellers and pleasure seekers are afraid to go to Granada, and those who do get there visit the Alhambra as quickly as possible and then hurry away, deeming themselves lucky if they only suffer from a passing attack of diarrhœa as the natural punishment for their imprudence in going to such a place. In these circumstances it would pay well to protect the water-supply and to substitute iron mains for the present system of open canalisation and porous pottery which along the whole of its course is accessible to contamination.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Birmingham and Midland Eye Hospital.

THE annual report of this institution, which has just been issued, alludes with satisfaction to the improvements in the out-patient department and to the new operating room which has been found of great service by the medical staff. The subscriptions have slightly increased during the past year but the donations and legacies have fallen off. The total payments for the year amount to £7800 5*s.*, an increase of £981 10*s.* 3*d.* compared with 1902. The total number of patients treated, exclusive of those on the books at the commencement of the year and exclusive of renewals, was 27,384, of whom 1022 were in-patients. The total number of attendances of out-patients was 65,394. No fewer than 731,345 patients have been admitted since the foundation of the hospital in 1823. A number of persons bringing out-patient tickets had been refused attendance on the ground that they were in a position to pay for advice. The committee expresses the hope that subscribers will endeavour to prevent the abuse of the benefits so liberally offered by the hospital. At the annual meeting of the subscribers to the hospital, the Lord Mayor, who presided, drew special attention to this part of the report. He was very sorry to see that the out-patient department was subject to abuse. It was, in his opinion, a great shame that any institution dependent upon public support should have to refuse cases in which patients were in a position to afford private treatment. That was one of the difficulties of the ticket system. It was the duty of the subscribers not only to give their subscriptions but also to see that the tickets were properly distributed. Under an ideal system they would not have tickets at all, but he feared that a great many subscribers would be apt to neglect the hospital if they were not constantly reminded of the usefulness of the institution by the demand for tickets.

The Birmingham Crematorium.

The new crematorium for Birmingham, occupying about an acre of ground in a country spot some distance from any dwelling-house and surrounded by trees, at Sheldon Coppice, near Rocky-lane, Perry Barr, is rapidly approaching completion and will be opened during the month of September by Sir Henry Thompson. The company which has provided it was founded in 1901 and Mr. F. B. Osborn was the architect. The chapel, which is approached by a gateway and drive from the main road, has a large porch or vestibule which is 50 feet by 25 feet and 40 feet high, with an open timbered roof. On one side are a vestry and registry office, with a separate entrance, and on the other side is a small mortuary chamber. The chapel is principally lighted by lofty clerestory windows and underneath these on both sides are recesses for the reception of urns containing the ashes of the dead. If relatives prefer it these urns can be placed in cloisters of ornamental design which they will be at liberty to erect in the grounds. The catafalque is placed at the end wall at the opposite side to the entrance and behind it is a window leading to the intermediary chamber. On the north-west side is a lofty ornamental tower, 80 feet in height, containing the stack. The temperature of the incinerating chamber will be about 2000° F.

Dinner to Dr. Alfred Hill, the Retiring Medical Officer of Health.

A dinner, at which an illuminated address was presented to Dr. Hill by the Lord Mayor, was given last week by Alderman Cook, chairman of the health committee. A number of members of the council and officials, including Dr. J. Robertson, the new medical officer of health, were present. In proposing the health of the guest of the evening, Alderman Cook said that Dr. Hill might be said to have seen almost the birth—certainly the beginning of organisation on anything like an adequate scale—of the sanitary department. At first the committee was called the borough inspection committee. Later it became the sanitary committee and after the Public Health Act came into force the health committee. He (the chairman) entered the council in November, 1872, and Dr. Hill was appointed medical officer in the December following. Their connexion had, therefore, been long. In those days there were only eight health inspectors, now there were over 30. It went without saying that the sanitary state of the city in those days was far from good. The death-rate was over 25 per 1000 and there were thousands of middens poisoning the air, the total area of which was reckoned at that time at about 13 acres. Nothing worse could be imagined. They had got rid of nearly all those middens and they were going in for further improvements. Alderman Cook also alluded to Dr. Hill's connexion with the closing of the city wells, the building of the city hospital, and other incidents of his career.

Vaccination Fees.

The attention of the board of guardians has been called by one of its number to the great increase in the amount of the vaccination fees which has been one of the results of the Act of 1898. Prior to that Act any person wishing to be vaccinated free of cost had to apply at the vaccination station; now the vaccination officer has to call if the authorities receive a notification to that effect, and it seems that many persons who formerly employed the family practitioner for this purpose now save his fees by engaging the services of the public official. Taking the four years prior to the Act of 1898 becoming operative, it is found that the fees paid in respect of the parish of Birmingham were respectively as follows: 1896, £387; 1897, £361; 1898, £345; and 1899, £293; or an average of £346 per annum. That was on a scale whereby the guardians paid 2*s.* 6*d.* for each successful vaccination. Under the new Act an order was issued by the Local Government Board making the minimum payment 5*s.*, in addition to which the surgeon receives 1*s.* for the registration of every child—whether vaccinated or unvaccinated—born in the parish should the baby reach the age of four months. As a result the aggregate of fees, which had been steadily declining, has much increased, as will be seen from the following totals: 1900, £1132; 1901, £1164; 1902, £1154; and 1903 (the official year ends on March 31st), £1877. This gives a yearly average of £1333, as compared with £346 for the preceding four years—an increase of practically £1000 per annum. The board of guardians has on various occasions complained to the Local Government Board as to the amount of the fees and has been met with replies that the communications have been received. At their meeting on July 29th the guardians passed a resolution pointing out that they had for the past five years called the attention of the Local Government Board "to the very excessive sums they have been compelled to pay in fees to the vaccination surgeon" and emphatically protesting against "the indifference with which these protests and remonstrances have been treated by the officials of the Local Government Board." The clerk was instructed to send this resolution to the Board in question.

August 4th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Aberdare Valley Colliery Surgeons.

UNTIL about three years ago the colliery surgeons in the Aberdare Valley received 2*d.* in the pound of the colliers' earnings as payment for their services. This poundage was increased to 3*d.* upon the representation of the surgeons that their out-of-pocket expenses had very considerably increased, noticeably in connexion with the salaries of their assistants. Within the past few months an agitation has been going on among the men employed in the Aberaman and Cwmaman collieries having for its object the adoption of a new scheme of medical attendance and at public meetings held on July 20th definite proposals which had been drafted by a committee of the workmen were approved. There are at present three surgeons engaged under the poundage system and they pay the whole of the expenses of their practices. Under the new scheme it is proposed to engage one medical officer at a salary of £600 per annum and five assistants each at a yearly salary of £200. The committee is to defray all the expenses of the undertaking, including the supply of drugs and instruments, stable expenses, house rent and taxes, and expenses of management. During the year ending June 30th, 1901, the poundage produced £4668 and it is estimated that under the altered conditions there will be a saving of £1500 or £2000, which sum it is intended to use in the maintenance of a cottage hospital. The scheme upon paper appears to work out well, but there are so many objections to its practical working that it is a little surprising to find it meeting with the approval of some of the leaders among the workmen. First of all the estimate of income is based upon the earnings of the men when wages were high and it is very doubtful whether this estimate will be maintained in the future; while a strike of any considerable duration would ruin the scheme. During the strike of 1898 for nearly six months many surgeons did not receive any payment at all from the colliers, although their surgery and other expenses were still going on and they continued to attend their patients. The proposal to employ assistants in place of some of the present surgeons is hardly likely to be satisfactory, if for no other reason than the constant change which will be taking place. A really satisfactory and competent assistant will not stay very long in a colliery district at a salary of £200 per annum when he can earn quite as much as, or even more, in a locality having pleasanter social and physical surroundings. Lastly, there is the question of the engagement and control of the assistants. If they are engaged by the committee of workmen difficulties of the gravest character will arise and the men may one day find the machinery of their medical service at a standstill. It would be interesting to know what the wives of the colliers think of the proposed alteration.

Butchers and Tuberculous Meat.

The butchers and cattle dealers of Cardiff, Swansea, and the surrounding districts are endeavouring to arrange a scheme whereby after a certain date no cattle above a given value shall be purchased either by auction or privately unless such cattle are warranted by the vendors free from tuberculosis. At a conference of butchers held at Cardiff on July 27th a committee of butchers, farmers, auctioneers, and cattle dealers was formed and a resolution was referred to them expressing the opinion that all cattle of not less value than £8 per head, calves and pigs of £1 10*s.*, and sheep of £1 sold in Glamorganshire or Monmouthshire should be guaranteed by the vendor free from disease. It was stated by one speaker that a large firm of Newport cattle dealers had instituted a system of insurance and during the past three years had paid £300 in compensation for cattle which had been sold by them and were ultimately found to be unfit for food.

Duties of a Workhouse Medical Officer.

An inquest was recently held on an old man who had died in the Newton Abbot (Devon) workhouse on a Sunday and the board of guardians, at their meeting, which took place on July 30th, were informed that the jury considered that the guardians should request their medical officer to visit the workhouse on Sundays in future. It was explained at the meeting that in such matters it was left to the discretion of the superintendent nurse to telephone to the medical officer if his attendance on that day was required and that there was not the slightest reason for him to visit in this instance, as the patient died from exhaustion due to old age. The guardians eventually resolved unanimously to let the communication lie on the table.

August 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal University of Ireland.

AT a meeting of the Senate of the Royal University of Ireland held on July 31st it was unanimously resolved, on the motion of Sir Christopher J. Nixon, M.D., to admit the veterinary profession to university status, subject, of course, to students fulfilling all the requirements as regards curriculum and examinations.

The Recent Epidemic of Small-pox in Dublin.

The small-pox epidemic has now completely disappeared from Dublin. The isolation hospital at the Pigeon House Fort has been evacuated and the convalescent patients at Bencavin will soon be discharged. Since the end of January 260 patients have been treated and there have been 34 deaths. The citizens have good reason to feel thankful that the disease has left them after six months instead of after its usual sojourn of years—this, moreover, notwithstanding the long delay and difficulty in obtaining an isolation hospital. It occurs to me that the lesson to be gathered from the happily short history of this outbreak is worth remembering, for it points with no doubtful finger to the prepotent efficacy of vaccination. Other means are valuable but Jenner's remedy remains, *longo intervallo*, easily the chief. It has of late years and recently been widely availed of in Dublin where the anti-vaccinationist is unknown and where accordingly a large amount of variolous immunity always prevails. Its value as a defence was clearly evident in this outbreak. Of the 260 patients who suffered not one proved to have been revaccinated and the entirely casualty list was practically supplied from unvaccinated patients. Vaccination really saved the situation and no unprejudiced observer can doubt in that regard the value of the enlightened advice of Dr. Walsh, the Roman Catholic archbishop, repeated every week to the ignorant poor of Dublin from pulpits in the city.

The Irish Medical Association and the Local Government Board.

The generous support which the medical profession and the Irish Medical Association have recently given to the claims of the Poor-law medical officers of Ireland has emboldened them to try to improve their position by means of parliamentary action. The Irish members of Parliament, however, have apparently failed to accomplish much for them. On July 30th Mr. Patrick O'Brien asked the Chief Secretary for Ireland whether he was aware that the Ballinasloe board of guardians had failed to procure a medical officer for the Killan dispensary district at a salary of £120 per annum; whether he could say if any medical men stated to that board in writing at what salary they would be willing to accept office, and, if so, at what amount; and whether he could say how many vacancies existed at present in the Irish dispensary service and for what period each district had been vacant, what fees were being paid per week to the temporary medical officers in charge of these districts, how much per week was paid in advertising the vacancies in each union, and how much of the total cost of locum-tenents' fees and advertisements was refunded by the Treasury to the guardians in each case. Mr. Wyndham replied that the vacancy in Ballinasloe union was created on June 20th. The guardians advertised for a medical officer at a salary of £120 a year. Two gentlemen offered their services at £200 a year. The guardians, however, decided to re-advertise at the former salary. There are eight other vacancies; two occurred in November last and the remaining six are of very recent creation. In reply to a further question by Mr. Delany as to whether those vacancies were caused by intimidation exercised by the Irish Medical Association the Chief Secretary made the following significant remarks:—

> I do not know that intimidation is the proper word. There have, however, been speeches made and resolutions passed suggesting that medical gentlemen should not accept appointments at less than £200 a year. I know that medical officers in Ireland have a great deal of [illegible] salaries are not high, but for [illegible] be more deserving of recognition [illegible] nd awaited the report of the Vice-[illegible] into the amalgamation of unions [illegible]

In THE LANCET of August 1st, under the heading "Parliamentary Intelligence" another question from Mr. Delany with the Chief Secretary's reply was reported. In reference to that case a special meeting of the Tullamore board of guardians was held on July 28th when the following letter was read from the Local Government Board:—

> With reference to the resolution of the Tullamore board of guardians of July 14th, the Local Government Board desire to state that the guardians should call on Dr. McCarthy to take up the duties of medical officer of Killoughey dispensary district. In the event of Dr. McCarthy refusing to do so the Local Government Board will direct a sworn investigation into the circumstances with a view to his removal from office by an order under seal.

Dr. McCarthy was accordingly called upon to take up the duties of the dispensary district. The chairman said that the trouble had now reached an interesting stage. After three attempts Dr. McCarthy was appointed but owing to the action of the Irish Medical Association he was intimidated from taking up the position. If he was now dismissed under seal he could never get any position under the Local Government Board of Ireland. It is obvious that the Irish Medical Association, with the eminent members of the medical procession connected with it, has now in its campaign in favour of the Irish union medical officers not alone the guardians to deal with but the Local Government Board as well, headed by the Chief Secretary for Ireland, who is of course its president.

Visit of the King and Queen to Cork.

Their Majesties the King and Queen visited Cork on August 1st and received a most enthusiastic reception. Addresses were presented by the corporate body of the Queen's College, by the Cork branch of the National Association for the Prevention of Consumption, and by the Cork Medical and Surgical Society. The College address having referred to the fact that the College was founded under the auspices of the late Queen Victoria went on to say, "And we confidently anticipate that under your Majesty's gracious favour it will continue to diffuse the light of learning throughout the province for the special benefit of which it has been established." The address from the Cork branch of the National Association for the Prevention of Consumption contained the following paragraph: "We are aware that the association which we represent owes its existence mainly, if not entirely, to the interest which your Majesty has unceasingly displayed in the welfare of your subjects by promoting the scientific and successful treatment of diseases which have been so long accepted as incurable." In the address from the Cork Medical and Surgical Society the following paragraph occurs: "As members of the medical profession we have been deeply interested in your philanthropic efforts to secure the better housing of the poor and to arrest the terrible destruction of human life caused by the ravages of tuberculosis and cancer. It also affords us much pleasure to know that Her Most Gracious Majesty the Queen is equally interested in all movements to eradicate disease and to alleviate suffering and misery." I ventured to prophesy some weeks ago that Their Majesties would receive a very hearty greeting in Cork because it was well known that His Majesty takes a deep personal interest in the people of this country and I am happy to be able to state that my anticipations have been entirely realised. Along the line of the Royal procession bunting was exhibited from nearly every window and handsome festoons stretched across the streets. All was brightness and colour and the cheering of the vast crowds afforded undeniable proof of the popular feeling. When driving through one of the principal streets it was noticed that the Queen directed His Majesty's attention to an inscription on one of the banners—"Welcome King Edward the Peace-Maker." The King smiled and was evidently pleased with the sentiment. Indeed, His Majesty repeatedly showed his high appreciation of the kindly feelings exhibited towards him and never lost an opportunity of expressing his ardent desire to make the people of Ireland happy, prosperous, and contented. The universal opinion entertained in Cork to-day is that King Edward the VII. by his tact, and especially by his kindliness of manner and desire to do good, has done much to secure that "union of hearts" which is so much to be desired in the interests of both countries.

The Belfast Workhouse.

In his half-yearly report Mr. Agnew, the Local Government Board inspector, recommended that a day nurse should be provided for patients in the female lock ward and that some effort should be made to supply an examination-room for gynæcological cases apart by itself. More baths were needed, he said, and the hope was expressed that the guardians might succeed in carrying out their laudable purpose of promoting a scheme for the modern treatment and complete isolation of consumptive patients. Mr. Agnew suggested that a sufficient addition be made to the nursing staff to enable the guardians to dispense entirely with pauper attendants, and he said that the medical, surgical, and nursing staff were zealous and skilled in the performance of their duties and that the patients were treated with every kindness and consideration. The board of guardians had decided to defer its reply to the letter of the Local Government Board inclosing the report.

August 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Institute of Legal Medicine and Mental Diseases.

THE Minister of Public Instruction by a decree dated June 22nd has approved of the resolution of the council of the Paris Faculty of Medicine relative to the creation and organisation in connexion with this faculty of an Institute of Legal Medicine and of Mental Diseases. The object of this institute is to give a theoretical and practical training to medical men and medical students, both French and foreign, who intend to practise as experts before the courts. A medical man or medical student, either French or foreign, who has gone through the course prescribed by the new institute and has passed a trial examination will receive a special diploma. A certificate of diligence will be given to foreign medical men and medical students who do not wish to undergo the trial examination. The new institute will be under the direction of the dean of the faculty of medicine, of the professor of legal medicine, and of the professor of the Clinique of Mental Diseases. The course of training will be divided into two portions: (*a*) a medico-legal training properly so-called and (*b*) a course of training in mental diseases from the medico-legal side. The training in regular medico-legal subjects will be under the direction of the professor of forensic medicine, who will take it in hand as a portion of the work attached to the chair of forensic medicine, together with (1) the *agrégés libres*; (2) the assistant director of the laboratory of toxicology; and (3) the assistance of the heads of the departments of anatomy and histology in connexion with forensic medicine. The course of training will include (*a*) a theoretical part and (*b*) a practical part. The theoretical part includes a complete course in forensic medicine. This course will be undertaken by the *agrégés libres* in connexion with the chair of forensic medicine and by the assistant director of the laboratory of toxicology. The practical part will include (1) the making of post-mortem examinations and the examination of living subjects with special regard to forensic medicine; and (2) microscopical, chemical, and physiological studies in so far as regards forensic medicine. This training will be given by the professor of forensic medicine, the *agrégés libres* in connexion with the chair of forensic medicine, and the heads of the various departments. The training in forensic medicine proper, both practical and theoretical, will be carried on for the whole of the duration of the stage of instruction—that is to say, during two terms of six months each. The medico-legal training in mental diseases will be under the direction of the professor of the Clinique of Mental Diseases who will give it (1) with the assistance of the *agrégés libres* and in connexion with the chair of mental diseases; (2) with the assistance of the medical instruction given by the medical officer of the infirmary attached to the depôt of the Prefecture of Police; and (3) with the assistance of the head of the clinique attached to the chair of mental diseases. The course of training comprises (*a*) a theoretical part and (*b*) a practical part. The theoretical part includes a complete course of instruction in mental diseases and in forensic medicine so far as regards mental diseases. This course of instruction will last during the first six months of the period of training and will be given by the *agrégés libres* in connexion with the chair of the Clinique of Mental Diseases and by the heads of the various departments in this clinic. The practical part will include (1) lessons and clinical demonstrations in mental diseases, which will be undertaken by the professor of the chair during the two periods of six months each during which the instruction lasts; and (2) clinical demonstrations in forensic medicine so far as regards mental diseases, which will be given during the second part of six months by the medical men attached to the special infirmary connected with the Prefecture of Police.

Obituary.

Professor Nocard of the School of Alfort, the eminent bacteriologist, who was one of Pasteur's colleagues at the commencement of the latter's investigations into the nature of serums, has just died at the age of 53 years after a short illness. He was born at Provins on Jan. 29th, 1850, and studied at the Alfort School, of which in 1878 he became *chef de service*. In the following year he was nominated to the chair of animal contagious pathology and sanitary police. In 1889 he was nominated as director of the whole establishment and held this post for many years until he gave it up in order to devote himself entirely to clinical research in the laboratory. He became in succession member of the Central Society of Veterinary Surgeons, of the Committee of Epizoötic Diseases, of the Committee of Hygiene of the Seine, and finally a member of the Academy of Medicine. In 1886 Professor Nocard became numbered among the most eminent bacteriologists owing to the results of the scientific investigation which, at the invitation of Pasteur, he undertook with Roux, Straus, and Thuiller, by the discovery which he then made of the microbe of farcy in the ox and of the bacillus of contagious mammitis in horned animals, especially in milk-giving cows. He also made researches in the nature of glanders (*morve*) and many other acute contagious maladies, especially pneumonia and aphthous fever. It is easy to recall his controversy with Koch, the German bacteriologist, in opposition to whom he, relying on his French experiments, maintained that it was possible to infect bovine animals with tuberculous matter taken from men. These statements refute in great part the theories of Koch as to the propagation of tuberculosis in man by milk or flesh of animals.

UNIVERSITY OF BRUSSELS.—The following is a list of English candidates who were successful at the June examination for the degree of Doctor in Medicine :—

Edward Cullinan, [illegible] Hospital ; Richenda Gillett [illegible] rnest C. Lambert, M.R.C [illegible] ; James C. McWalter, M.A., L.R.C.S.I., F.F.P.S. Glasg., D.P.H., Catholic University, Dublin ; Cecil E. J. Philippson, F.R.C.S., Cape Town ; and *George Sowden, M.R.C.S., L.R.C.P. Lond., D.P.H. Cantab., London Hospital.

* Passed with honours.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Ludwig Blumreich has been recognised as *privat-docent* of Gynæcology, Dr. Richard Cassirer as *privat-docent* of Nervous Diseases, and Dr. Wilhelm Stoeltzner as *privat-docent* of Children's Diseases.—*Budapest:* Dr. F. Reuss has been appointed Lecturer on the Biology of the Nervous System.—*Erlangen:* The chair of Medicine recently held by Professor Penzoldt has been filled by the appointment of Professor Fritz; in consequence of Professor von Strümpell's removal to Breslau Professor Ernst Graser has been appointed Director of the University Hospital.—*Halle:* The chair of Psychiatry having been declined by Dr. O. Binswanger has now been offered to Professor Ziehen of Utrecht.—*Heidelberg:* Dr. Otto Cohnheim, *privat-docent* of Physiology, a son of the late Professor Cohnheim, has been promoted to an Extraordinary Professorship.—*Leipsic:* Dr. F. Rolly has been recognised as *privat-docent* of Internal Medicine. Dr. Risel has been appointed Prosector to the Pathological Institute in succession to the late Professor Saxer.—*Prague (German University):* Dr. Josef Langer has been recognised as *privat-docent* of Children's Diseases.—*St. Louis:* Dr. Hugo Ehrenfest, who has been operator in the Vienna Gynæcological Clinic under Professor Schauta, has been appointed Instructor in Obstetrics.—*Strasburg:* Dr. Ulrich Rose has been recognised as *privat-docent* of Medicine.—*Vienna:* Dr. Stefan Weidenfeld has been recognised as *privat-docent* of Dermatology and Syphilis; Professor Albert Neisser of Breslau has been selected for the offer of the chair of Dermatology, which is being vacated by the retirement of Professor Isidor Neumann.—*Wurzburg:* Dr. A. Schmincke has been appointed Prosector to the Institute of Comparative Anatomy.

QUEEN CHARLOTTE'S HOSPITAL.—Viscount Portman, the President of Queen Charlotte's Hospital, took the chair on July 23rd, at a meeting held at his house, 22, Portman-square, on behalf of this hospital. In consequence of the great increase in the work of the charity it has been decided to enlarge the Nurses' Home at a cost of £2000. Lord Hardwicke, the chairman of the committee of management, wrote regretting his inability to be present and stating that the in-patients had increased from 692 in 1882 to 972 in 1892, and 1271 in 1902, while during the first six months of the present year the number was 722. The Bishop of Kensington moved—

> That this meeting of governors and friends of Queen Charlotte's Hospital desires to express its continued interest in the charity and having regard to its great and growing work to commend to public support the efforts now being made by the committee to provide the further increased accommodation necessary for patients and nurses, and to obtain the additional funds needed for maintenance.

The motion was seconded by Lieutenant-General Lowry and carried.—Mr. H. A. Harben moved :—

[illegible]

Dr. W. Rivers Pollock, in seconding the motion, stated that Queen Charlotte's Hospital was the largest lying-in hospital in Great Britain and that it offered exceptional facilities to medical students and qualified practitioners in obtaining a knowledge of practical midwifery and of the treatment of very young infants. The motion was carried and a vote of thanks to Lord Portman for kindly lending his house for the meeting and for presiding brought the proceedings to a close.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—On July 21st Dr. R. Roxburgh, president of the Weston-super-Mare Philharmonic Society, was presented with a silver-mounted writer's companion, together with an illuminated address expressing the respect and esteem of the members for one who has for many years occupied the presidential chair of the society.—On July 15th Dr. J. H. Stowers was presented by his colleagues at the North-West London Hospital with a silver salver, the inscription on which explained that it was given "as a token of friendship and in recognition of 17 years' service as honorary secretary to the medical committee."—On July 29th Dr. C. A. Hayman was presented with a silver cigar case in recognition of his work in connexion with the Bristol Corps of the St. John Ambulance Brigade. Mrs. Hayman was also presented with a silver jewel-box.

Kingsbridge Cottage Hospital.—The annual meeting of the subscribers of the Kingsbridge (Devon) Cottage Hospital was held on July 22nd. During the past year the new wing of the building, which has been erected by Mrs. Berks, was opened. It contains a male ward and female ward, each for three beds, and an operation-room. During the past 12 months 39 in-patients were admitted. There was a favourable balance of £13 remaining, which may not seem a great sum, but it is always pleasant to chronicle a surplus, however modest.

Müller's Orphan Houses. — The report of Müller's Orphanage at Bristol has just been issued and shows that the institution has now entered on its seventieth year of existence. During 1902 the sum of £37,013 was received for the orphans and £4778 for other work in connexion with the institution. Five years have now passed since George Müller died and there has been no sort of organised or direct appeal to the public or any individual for subscriptions, and yet every agency has been efficiently maintained. The report alluded to the resignation of Dr. Eubulus Williams, who has been physician to the orphanage for the past 34 years, and adds that Dr. C. O. Bodman has been appointed to the post thus rendered vacant.

University of Durham College of Medicine, Newcastle-upon-Tyne.—During the last 12 months there has been a slight decrease in the number of specimens examined in the Bacteriological Diagnosis Department of the University of Durham College of Medicine, Newcastle-upon-Tyne. Some of these examinations have been made for medical practitioners, others by special arrangements for the county councils of Northumberland and Durham, the Guisborough combined district councils of the North Riding of Yorkshire, the town councils of Sunderland and West Hartlepool, the Newcastle Royal Infirmary, and other public institutions. The total number of specimens examined in the laboratory during the year ending May 31st, 1903, amounts to 938, as compared with 1009 during the preceding 12 months. The different kinds of examinations carried out were as follows: 513 samples of sputum from suspected cases of phthisis were examined for tubercle bacilli, which were found in 218 cases; 101 specimens of blood were examined from suspected cases of enteric fever by Widal's method, a positive result being obtained in 44 cases; 205 swabs from suspected cases of diphtheria were examined for the bacilli, which were found in 66 specimens; ten specimens of pus were examined, the pneumococcus being found in two, streptococcus pyogenes in three, staphylococcus pyogenes aureus in four, and the gonococcus in one; tubercle bacilli were found in one specimen of urine and in one of fæces; eight specimens of anthrax were examined, positive results being obtained in four; and 50 samples of water were examined quantitatively for bacteria.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Thursday, July 30th.

Cholera at Quetta.

Mr. Schwann asked the Secretary of State for India whether any report had been received from the chief medical officer at Quetta or through the political department at Simla regarding the outbreak of typhus fever amongst the workmen on the Nushki-Seistan railway route and of cases of cholera at Quetta, and whether a report could be presented showing what progress had been made with the earthwork on that desert route, and describing the sanitary conditions and the question as to water-supply that were likely to affect the construction of the line and the future facilities for traffic such as the Nushki-Seistan railway was intended to offer.—Lord George Hamilton: A railway is being constructed from Quetta to Nushki but no proposal for its extension from Nushki towards Seistan has been made or sanctioned. I have no information as to the prevalence of epidemics among the workers on the Quetta-Nushki Railway but I have heard that there is an epidemic of typhus fever at Quetta and in other parts of Baluchistan. Cholera is also reported near Quetta and at Nushki.

Ambulances in Hyde Park.

Mr. Claude Hay asked the hon. Member for West Derbyshire, as representing the First Commissioner of Works, whether the St. John ambulances in Hyde Park have been decided upon as being as satisfactory as the Metropolitan Police ambulances in Hyde Park, and whether he would state the result of the promised inquiry as to the number and positions of ambulances which were placed in Hyde Park, having regard to recent accidents to horsemen and others.—Mr. Victor Cavendish: The St. John ambulances in Hyde Park have been inspected by Sir William Bennett who reports that they are not quite so satisfactory as the Metropolitan Police ambulances, but owing to their lightness and simplicity they are best suited for the purposes of work in Hyde Park. There are now ambulances at Alexandra Gate, Hyde Park Corner, the Marble Arch, and at the police station.

Medical Officers in Ireland.

Mr. Patrick O'Brien asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that the Ballinasloe board of guardians had failed to procure a medical officer for the Killan dispensary district at the salary of £120 per annum; whether he could say if any medical men had stated to that board in writing at what salary they would be willing to accept office, and, if so, at what amount; and whether he could say how many vacancies existed at present in the Irish dispensary service and for what period each district had been vacant, what fees were being paid per week to the temporary medical officers in charge of these districts, how much per week was paid in advertising the vacancies in each union, and how much of the total cost of locum-tenents' fees and advertisements was refunded by the Treasury to the guardians in each case.—Mr. Wyndham: The vacancy in Ballinasloe union was created on [illegible] remaining six are of very recent creation. Temporary medical officers are usually paid £4 4s. a week. The cost of advertisements is not officially known. Recoupment is made in respect only of approved salary.

Haffkine's Plague Prophylactic.

Mr. Weir asked the Secretary of State for the Colonies whether he would state on what date the system of inoculation with Haffkine's plague prophylactic was brought into operation in Hong-Kong, the number of persons inoculated, and how many have since succumbed to plague.—Mr. Chamberlain: I have no information on the point but will ask the Governor for a report.

Monday, August 3rd.

Medical Reports.

Mr. D. A. Thomas asked the President of the Local Government Board when the sixty-f[illegible]rths, deaths, and marriages (England)) of [illegible] 1901, presented on August 4th, 1902, and whe[illegible] thirty-first annual report of the Local Government Board, 1901–02, containing the report of the medical officer for 1901–02, presented Nov. 3rd, 1902, would be delivered; whether he could say what had been the cause of the delay in the publication of these reports; and whether he would take steps to alter the practice of presenting command papers in dummy in one session when not ready and not delivering them until the next in view of the inconvenience involved.—Mr. Long replied: As regards the annual report of the Registrar-General, I am informed that it will be issued with very little further delay. The Registrar-General states that the report has been delayed exceptionally this year on account of the heavy pressure in his office due to the preparation of the Census returns and also to an important change which it has been found necessary to make in the tabulation of deaths. The report of the medical officer of the Local Government Board, to which the honourable Member refers, has gone to press and will, I understand, probably be issued within a month. The issue of the report this year has been delayed through the amount of special work which has been thrown on the medical branch in connexion with the recent small-pox epidemic. I am desirous that reports which are presented in dummy should be issued as soon as possible afterwards; but, as the honourable Member will see, the delay in the present cases was due to exceptional circumstances.

The Army Medical Service.

On the vote of £530,000 to defray the charges for the Army Medical Service Mr. Burdett-Coutts initiated an interesting debate. He gave Mr. Brodrick credit for much energy in reform and several important results, but he contended with emphasis that "the only way to escape from the fatal cycle of medical disaster and attempted reform which had marked the last 60 years was a thoroughly organised system of civilian aid."—Mr. Brodrick said that he fully recognised the services which Mr. Burdett-Coutts originally rendered in bringing forward the question of army medical reform. In the changes that had been made everything had been done to see that the arrangements did not become stereotyped, and in order to avoid that he had enlisted the leading members of the medical profession who were in closest touch with the medical developments of the day. He had been peculiarly fortunate in this respect. He invited the assistance of some of the most eminent members of the profession and he could not express too highly his gratitude to those gentlemen who had given up high fees and personal practice to sit with him on a committee and had also offered themselves as willing to act on the Advisory Board at a merely nominal honorarium. In order that the Army Medical Department might be adequately reorganised, besides the army members, the Advisory Board consisted of eminent civilian physicians and surgeons who attended three or four committee meetings weekly. The War Office had endeavoured to meet their views in regard to pay, the increase of numbers, and the increase of leave for study in the military college, for which a site had been secured. Previously to the appointment of the Advisory Board the number of candidates was not equal to half the vacancies, but since then the numbers had increased and at the last examination there were [illegible] candidates for 30 vacancies, some of the candidates having occupied positions in the best hospitals. The Advisory Committee had reviewed the whole of the military hospitals in the country and he hoped that they were on the eve of very great changes in not treating so many trifling cases, having a much better equipment, more scientific structures, and a general modernising of the institutions. He had asked Parliament to vote £150,000 which he proposed to intrust to a small committee, of which Sir E. O. Perry would be chairman, and that committee would apportion the money among the various military hospitals with a view to secure their modernisation. Another point was the organisation of an adequate civilian reserve and the definition of its status as compared with the Army Medical Corps itself. He hoped next session to be able to state that these were accomplished facts.

Appointments.

[illegible] ublic Institutions, [illegible] this column, are [illegible] rected to the Sub- [illegible] morning of each [illegible]

Barber, G. W., M.R.C.S., L.R.C.P. Lond., has been appointed, *pro tem.*, Acting Resident Physician to the Kalgoorlie Hospital, West Australia, and also Acting District Medical Officer, *pro tem.*, of Kalgoorlie.

Belgrave, T. B., M.R.C.S., M.D. Syd., has been appointed Visiting Justice to the Gaols in East Kimberley, West Australia.

Birkbeck, Lawrence Henry Carr, M.B., B.S.Oxon., has been appointed Medical Referee under the Workmen's Compensation Acts, 1897 and 1900, for Bridgwater, Chard, Langport, Wellington, and Williton.

Black, Victor, M.B., Ch.M. Edin., has been appointed Officer of Health, *pro tem.*, of Perth, West Australia.

Boycott, A. E., M.A., M.B., B.Sc. Oxon., Fellow of Brasenose College, has been appointed Gordon Lecturer in Experimental Pathology at Guy's Hospital Medical School.

Bruce, R. T., M B, M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Thames District of the County of Oxford.

Campbell, Peter, M.B. Edin., has been appointed Certifying Surgeon under the Factory Act for the Newport District of the County of Fife.

Cuff, Archibald, B.A., M.B., B.C. Cantab., F.R.C S. Eng., has been appointed Surgeon to the Royal Infirmary, Sheffield.

Dawes, R. St. M., L.R.C.P. Lond., M.R.C.S., has been appointed Health Officer of Gawler South, South Australia.

Elliott, Charles Bolton, L. & L Mid. R.C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health of Geraldton, West Australia.

Harratt, T. T., M.R.C.S., L.R.C.P. [illegible] ointed [illegible] rict of [illegible]

Hop [illegible] Medical [illegible]

Howard, T., M.B., B.S. R.U.I., has been appointed Certifying Surgeon under the Factory Act for the Portland District of the County of Dorset.

Kelly, T. Gordon, B.A., M.D., D.P.H., has been re-appointed Medical Officer of Health of the Market Bosworth Rural District.

Lemarchand, Arthur Wharton, M R C.S., L R C.P. Lond., has been appointed Medical Referee under the Workmen's Compensation Acts, 1897 and 1900, for Barnstaple, B[illegible]eford, South Molton, and [illegible]

[illegible] has been appointed [illegible] Henrietta-street, W.C.

[illegible] been appointed Assistant [illegible] London.

[illegible] been appointed Honorary [illegible] rth Public Hospital, West Australia.

Roberts, R. L., has been appointed Certifying Surgeon under the Factory Act for the Ruabon District of the County of Denbigh.

Simpson, Lilian G., M.D. Brux., L.R.C.P. & S. Edin., has been appointed Assistant Medical Officer to the Camberwell Infirmary, Camberwell, S.E.

Stirling, Edward Charles, C.M.G., F.R.S., M.D. Cantab., has been appointed Honorary Consulting Surgeon to the Adelaide Hospital, South Australia.

Walker, J. W. Thomson, M.B., C.M. Edin., F.R.C.S. Eng., has been appointed Assistant Surgeon to St. Peter's Hospital, Henrietta-street, W.C.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

West African Medical Staff, Colonial Office, S.W.—Seven Medical Officers. Salary £400 to £500 a year, with quarters, &c.

Births, Marriages, and Deaths.

BIRTHS.

[illegible] e wife of Octavius [illegible]

[illegible] ngton, the wife of [illegible]

[illegible] Hyde-park, W., the wife of Reginald Hartley, M.D. Durh., F.R.C.S. Edin., of a daughter.

Pilcher.—On July 30th, at Boston, Lincolnshire, the wife of Cecil Westland Pilcher, M.R.C S., L.R.C P. Lond, of a son.

Turner.—On July 30th, at Grafton House, Buxton, to Mr. and Mrs. Turner, a daughter.

MARRIAGES.

Baker—Hindley.—On July 30th, at the Church of St. [illegible] ary, Plaistow, Kent, Arthur Ernest Baker, M.R.C.S., of 44, Brook-street, London, W., to Agnes Flora, youngest daughter of the late Charles H. [illegible]

[illegible] J.P., Crichton House, Dumfries.

[illegible] George's, Hanover- [illegible] Morrison, M.D., of [illegible] Frances, youngest [illegible] of Southsea.

DEATHS.

[illegible] e six, the [illegible] C.P. [illegible] enderson, [illegible] Maritime [illegible]

[illegible] Matthias [illegible] hire, late [illegible]

Swayne.—On August 1st, at Pembroke-road, Clifton, Bristol, suddenly, Joseph Griffiths Swayne, M.D. Lond., M.R.C.S., L.S.A., in his 84th year.

Walker.—On the 17th inst., suddenly, Hunter Urquhart Walker, L.M., L.R.C P., L R.C S. Edin, of 1, Pembury-road, Clapton, son of the late Rev. Alexander Walker, for many years Senior Chaplain of the Scottish Church, Madras Presidency, and lately Minister of Rescobie, Forfarshire.

Weaver.—On the 1st inst., at Westbrook, Southport, James Weaver, M.D., aged 71 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A LAY VIEW OF THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—The following cutting from the *Globe* I think illustrates the attitude adopted by a large number of people in this country:—

> A better illustration of truly paternal legislation could hardly be found than in the attempt of the German Federal Council to prohibit the sale of certain well-known patent medicines in Germany. Apparently a man may not now even drug himself to his liking in that most official land, and if some unauthorised person discovers a really valuable remedy of which the doctors cannot ascertain the ingredients, and therefore violently disapprove, no German can obtain the benefit of it. Our own system has its defects, but it is at least a very long way superior to this.

The paragraph shows not only an utter want of appreciation of the damage to person and pocket that patent medicines may do, but a forgetfulness bred of inexcusable ignorance of the fact that the "man in the street" cannot possibly be a judge of what drugs he should give himself, and that laws such as the one referred to protect those who are unable to protect themselves. The words "therefore violently disapprove" show that the writer of this paragraph has an utterly perverted idea of the attitude of the medical profession upon self-drugging and quack medicines.

I am, Sirs, yours faithfully,
August 1st, 1903. A. W. F. (M.D.)

⁂ We assume that our correspondent, with whose views we agree in the main, is advocating similar legislation in this country. But as long as any person, however ignorant, is allowed to prescribe for his fellows it is hopeless to expect any Government to try to protect foolish people against themselves. The view of the writer in the *Globe* is not that taken by the better instructed portion of the laity.—ED. L.

"A DANGEROUS PAMPHLET."

To the Editors of THE LANCET.

SIRS,—In consequence of the article which appeared in THE LANCET of August 1st, we have discontinued to supply the pamphlet complained of except to medical men. Copies have been given to the public on their request, mostly to readers of the *Scotsman*, in consequence of a letter appearing in it on July 13th last and also one on August 19th, 1902. Not more than 70 or 80 have been sent out in this way and in all cases they have been applied for. We have never circulated this pamphlet broadcast but have sent out one with each pipe; we have supplied these pipes to medical men and to their order since 1878, with the exception of about a dozen, and these were sold on the recommendation of those who had themselves used them—in some cases foreigners—at intervals. We are sorry indeed to find that our action is so strongly disapproved—we hope under a misapprehension of the facts. The members of the medical profession have hitherto been our best friends and we most sincerely hope will continue to be so.

We are, Sirs, yours faithfully,
GAMBLE AND CO.
Edwardes-terrace, Kensington-road, W., August 2nd, 1903.

ST. FRANCIS HOSPITAL FOR INFANTS.

To the Editors of THE LANCET.

SIRS,—I have received a circular letter from Mellin's Food, Limited, in which the St. Francis Hospital for Infants is referred to. Reference is also made to statements occurring in the speeches of Dr. Henry Ashby and myself on the occasion of the opening of the hospital. The general tenour of this document may lead some members of the profession to think that the hospital is in some way connected with the use of the preparation known as Mellin's Food. I therefore desire to prevent any misconception on this matter. It has never been used in the hospital.

I am, Sirs, yours faithfully,
Harley-street, W., July 31st, 1903. RALPH H. VINCENT.

A STORY OF THE EARLY PART OF THE NINETEENTH CENTURY.

To the Editors of THE LANCET.

SIRS,—I was much interested in the letter of a lay correspondent published in THE LANCET of July 25th, p. 278, which gave a short description of the mode of practice of the so-called "Whitworth Doctor" of Oldfield Lane. His description is fairly true, but not all of it. One brother, F. S. Taylor, died at the residence of his son in Sheffield in October, 1866, in my presence (where I was an assistant), nearly 90 years of age. He left seven sons, five of whom qualified in medicine, and all did well. Two followed the bone-setting business, but neither of them with the success of their progenitors. It was not in the Epsom salts and antimonial purgations that their success lay, but in the celebrated black plaster and red bottle. This was compounded of ingredients purchased separately at different druggists in Leeds and London and mixed by themselves at midnight, and if it had no other merit it never disagreed with any skin and was never followed by any pustulation. I saw much of bone-setting so-called and treatment of injuries to joints that would be of great value to many country surgeons, and so much did I interest myself in the craft that I was offered to be initiated into the secret if I would take the pledge of secrecy. This I declined to do and I fancy the secret died with the death of my preceptor, which took place somewhere about 1880.

I am, Sirs, yours faithfully,
August 3rd, 1903. F. A. D. GODFREY, L.R.C.P., L.R.C.S. Edin.

A NEW LIGHT AND COLOUR BATH.

To the Editors of THE LANCET.

SIRS,—I am desirous of bringing before the notice of the profession a new light bath made to my order by the Sanitas Electrical Company, Soho-square. It is a reclining one, fitted with both the arc and the incandescent light. The lamps of the latter are of three colours—red, blue, and ordinary white; either series of colours can be switched on separately. A more extended use of the electric light bath has confirmed me in my opinion on the following points: 1. The therapeutic action of the incandescent lamps is chiefly sudatory. 2. Blue rays act well in many neurotic cases, chiefly by suggestion. 3. The arc light (and heat therefrom) is a successful curative agent in rheumatism, gout, myalgias, psoriasis, catarrh, &c. In acute laryngitis I have seen very good results. 4. As a general tonic the light bath is superior in every way to the Turkish bath.

I am, Sirs, yours faithfully,
J. STENSON HOOKER, M.D. Durh.
Gloucester-place, W., July 27th, 1903.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Can any reader of THE LANCET kindly recommend a home for a man with hemiplegia and delusions? He can pay from £1 to £1 10*s*. a week.

I am, Sirs, yours faithfully,
36, Albert-street, Rugby, July 17th, 1903. M.R.C.S.

ERRATUM.—Mr. S. R. Scott writes:—With reference to my article on a Modification of Roughton's Splint for Pott's Fracture, in THE LANCET of August 1st, p. 323, may I point out a small error. In line 16 of the article, which reads thus: "being to avoid an extended or inverted position of the foot," "inverted" should read *everted*.

◆

V. E.—From the information before us we consider that the assistant is entitled to the fees in so far as regards patients notified by himself. The matter, though a small one, should form the subject of future arrangement between the head surgeon and the assistant surgeon

C. M. W.—We do not know of any such institution for nurses solely, but as regards hospital nurses some hospitals have convalescent homes attached to them to which the nurses can go in case of need.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (10th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—3 30 P.M. Dr. Davis: Medical Cases. (Medical wards.)

TUESDAY (11th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Heart Disease in Children.

WEDNESDAY (12th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Armour: Suppurative Diseases of the Central Nervous System.

THURSDAY (13th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—4 P.M Mr. Edwards: Surgical Cases. (Surgical wards.)

FRIDAY (14th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Ball: Discharge from the Ear: Causes and Treatment.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1903, which was completed with the issue of June 27th, and the Title-page to the Volume, were given in THE LANCET of July 4th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1903 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

The Milroy Lectures
ON
THE CAUSES, PREVALENCE, AND CONTROL OF PULMONARY TUBERCULOSIS.

Delivered before the Royal College of Physicians of London on March 5th, 10th, and 12th, 1903,

By H. TIMBRELL BULSTRODE, M.A., M.D. Cantab., D.P.H.,

INSPECTOR, MEDICAL DEPARTMENT, H.M. LOCAL GOVERNMENT BOARD; LECTURER ON PREVENTIVE MEDICINE, CHARING CROSS HOSPITAL MEDICAL SCHOOL.

LECTURE III. (*continued*).[1]

Delivered on March 12th.

Certain English Sanatoriums.

I am afraid that the facts which I propose to bring to your notice with regard to sanatoriums may prove somewhat disappointing to those who are alone familiar with the palaces in Germany and with some of the elaborate private sanatoriums of this country. Those, too, who are connected with the King's Sanatorium scheme may, I fear, be almost disposed to cast ridicule upon the relatively humble buildings with which I propose here to concern myself. But as my remarks must be limited I can deal only with one aspect of the problem and I therefore propose to select for consideration sanatoriums which are intended for those other than the rich or comfortably circumstanced. My interest and my work lie rather in the public aspect of the problem. I shall therefore omit all references to private institutions and deal only quite incidentally with what is being done by means of private munificence. By private munificence I have in mind rather sanatoriums such as the King's Sanatorium and those institutions which have been, or are being, erected in Delamere Forest for the relatively poor of Liverpool and Manchester. All honour to the founders and promoters of these and similar institutions, but such institutions are the results of an uncertain and spasmodic force the future behaviour of which cannot be predicted or reckoned upon.

I propose, therefore, to draw attention to what is being done in certain of the counties of this country in a more or less systematic fashion. All these efforts appear, so far as I can judge, to be due, at any rate in the first instance, to the foundation of a local branch of that admirable organisation the National Association for the Prevention of Consumption and other Forms of Tuberculosis. I say this because I desire to accord the credit to the organisation which appears to me to be responsible for at least the initiation of practically all the schemes to which I am about to refer. At present there are but few sanatoriums which have been thus brought into existence, but there is, I think, every prospect that the number will be shortly materially augmented. The example has been set by the vigour of several of our northern counties, and the vigour of the north seems gradually to be extending to the south, as is borne witness to by the fact that since this lecture was delivered a committee of the three counties of Wilts, Somerset, and Gloucester has, largely through the efforts of Dr. Lionel A. Weatherly, laid the foundation-stone of a sanatorium for the tuberculous poor of this district on what Dr. J. Tubb-Thomas, the Wiltshire county medical officer of health, tells me is an ideal site of 50 acres at Winsley, near Bath. This scheme has been promoted mainly by public subscriptions, but several sanitary authorities, including those of Bristol, Bath, Swindon, and Gloucester, have made arrangements to maintain beds, as also have certain business firms and companies, among them being the Great Western Railway Company. I learn also from a report kindly sent to me by Dr. F. G. Bushnell that a sanatorium has been recently opened at Didworthy, near Brent, for the use of consumptives in the counties of Devon and Cornwall. In connexion with this institution the Plymouth board of guardians propose to subscribe for the use of one bed. In Dorsetshire Lord Ilchester has given a site and a donation for the purpose of aiding the erection of a sanatorium for the poor of that county. In Hampshire Dr. A. Mearns Fraser has endeavoured to bring about the erection of a county sanatorium, but his efforts have not as yet received the support they deserve. In Wales there are indications of progress.

But the sanatoriums to which I propose specially to refer are (1) the Westmorland Sanatorium, (2) the Durham Sanatorium, (3) the Nottingham Sanatorium, and (4) the Worcestershire Sanatorium. I have selected these institutions after visiting practically all the public sanatoriums in this country, because I think they afford the most useful lessons for future work.

The first two of these had for their beginning an existing mansion; the latter two are practically new structures. Now all four of these institutions have been originated and are carried on by local philanthropy of an administrative and pecuniary nature. But as time goes on they are tending in some degree to become what I may call semi-public institutions—that is to say, the local sanitary authorities are contributing towards the annual expenditure of the institutions and are also in some cases making such an annual contribution as to secure for themselves the right to nominate patients for one or more beds.

The Westmorland Sanatorium.[2]—I have found considerable difficulty in selecting the sanatorium the details of which in the first place to bring before you, but I think that the Westmorland Sanatorium conforms most closely to the type which is evidently, whether consciously or unconsciously, being kept in view in other schemes. My main reason, however, for selecting the Westmorland Sanatorium is not on account of the nature of the building or the excellence of the site but because its committee has up to the present succeeded better than any other in procuring the coöperation of the local sanitary authorities more immediately interested in the institution. Other schemes have developed, and are developing, upon the same lines and some of them may eventually afford better illustration of the principle I am now discussing. In what I shall have to say and to show with respect to this sanatorium I am much indebted to Dr. W. Rushton Parker who has done such excellent work in promoting the institution which owes its origin very largely to the generosity of another member of our profession, Dr. W. S. Paget-Tomlinson.

The Westmorland Sanatorium, which is erected in a picturesque position at an elevation of 110 feet and on a limestone rock formation, overlooks Morecambe Bay. It is two miles from Grange-over-Sands and 11 miles from Kendal. The sanatorium was i [illegible] home for 16 patients, [illegible] at an expenditure of [illegible] building for 16 consun [illegible] There is now, in 1903, accommodation for 24 patients—i.e., eight in each of two wards and two in each of four sleeping shelters. But the point to which I wish particularly to draw attention in connexion with this institution is that no fewer than 21 of these beds have been appropriated by various local authorities in the county at a rate of £60 per annum for each bed. This fact is brought out by the first of the following tables. As the average cost of maintenance, however, is about 36*s.* a week there is a heavy deficit arising out of the arrangement to allow beds to be appropriated at 25*s.* a week, and as the 24 beds have never yet been filled by patients from within the county of Westmorland what may be called "outsiders" are taken in at a charge which provides a slight margin of profit.

The usual length of stay in the early cases is 12 weeks, in the moderately advanced 18 weeks, and in the quite advanced cases 24 weeks. The result of the three years' working shows that the vast majority of those admitted in the early stages, even after an average stay of three months, recover and are able to return to some years of useful work. Of the moderately advanced cases, where the average stay of the patient is four and a half months, a considerable but smaller number are able to do some useful work, though many relapse and some few soon die. The majority of the patients in the advanced cases die within a year, even after six months' treatment, and only a very small minority return to any useful occupation. The further experience of this sanatorium has been that much of the curative value of the institution is diminished by the presence of the advanced cases which although staying some six months in the institution are of but little use in a working sense thereafter. In order to surmount this difficulty efforts are being made to procure accommodation at some place other than the sanatorium for the relatively hopeless cases. The county council has taken the matter in hand and there is apparently a fair prospect that in the near future some such provision will be made. I have thought that it might be both useful and interesting were I to give here a table from the last annual report of the Westmorland Sanatorium showing the source of income and the expenditure (Table I.), as also other tables (Tables III., IV., and V.) with regard to the history of the several groups of patients. We are probably all familiar with tables relative to German sanatoriums, but the Westmorland figures will have greater interest for Englishmen. I venture to think that these tables may be very instructive reading to many persons outside the limits of our own profession. The table relating to "consumption slight" (Table II.) is of great interest as an illustration of the importance of securing patients in the earliest stage of the malady. In each class the cases are marked off into three distinct years. It is important to note that throughout the tables where tubercle bacilli are "not found" it is not invariably the case that they have been diligently sought.

---

[1] Lecture I., the first and second parts of Lecture II., and the first part of Lecture III., were published in The Lancet of July 11th (p. 73), 25th (p. 206), and August 1st (p. 297) and 8th (p. 361), 1903, respectively.

[2] This lecture was illustrated by numerous lantern slides relative to British and foreign sanatoriums.

The Durham County Sanatorium.—This institution, which was founded in 1900 by the Durham branch of the Society for the Prevention of Consumption and other Forms of Tuberculosis, is situated just outside the village of Stanhope in the Wear valley, and Mr. John Gray, the medical officer, was good enough to show me over the institution and to furnish me with photographs which I now exhibit. The site, which is an attractive one, consists of two and a half acres of land at an elevation of some 700 feet above ordnance datum and the neighbourhood of the sanatorium is admirably suited for the exercise of the patients. It is well protected both naturally and by means of a high wall which encircles the grounds. The main building consists of a country house altered in such fashion as to serve the needs of an open-air sanatorium. A new wing has now been added and this, with the addition of a detached building which has been converted into bedroom accommodation, brings the total number of beds up to 29—i.e., 20 for females and nine for males. It is hoped soon to extend the buildings so as to provide for 40 patients. The house and grounds are at present held on an 80 years' lease at a rental of £35 per annum. The sanatorium is supported by the payments of patients, by subscriptions from local sanitary authorities, from industrial societies and other groups of workmen, as also by voluntary subscriptions. For instance, the income for the year ended April 30th, 1902, was £1556 17*s* 4*d*, and towards this sum the following amounts were contributed weekly payments by patients, £840 15*s* 10*d*, payments of bodies of workmen, £301 18*s*, from local authorities, £170, and from annual subscribers, £189 15*s* 6*d*, making a total of £1502 9*s* 4*d* The weekly charge for those patients who are able to pay is £2 but the committee has discretionary power to remit either the whole or part of this sum As a general rule, no patients are allowed to stay longer than 16 weeks and the same patient cannot, except in exceptional circumstances, be admitted twice in the same year

Dr William Robinson of Sunderland, to whose efforts the erection of the sanatorium is in large part due and to whom I am indebted for the information here given, tells me that during the first year with 12 beds, the weekly cost per patient was 31*s* 10*d*, during the second year, with 18 patients, about 28*s*, and it is expected that with 29 patients the cost will work out at about 25*s* These figures include all expenses By the scheme of maintenance adopted the sanatorium is almost self supporting, only one sixth of the income coming from private subscriptions The committee may therefore claim to have solved the difficulty of maintaining a sanatorium for the working classes I give further on a table (Table VI.) taken from the medical officer's last annual report.

The Nottinghamshire Sanatorium —My object in bringing this sanatorium to the notice of the College is that the institution, which was founded in 1901, largely through the efforts of Dr W B Ransom of Nottingham, for persons of limited means, affords an illustration of the cost of what is known as a "temporary"—i e, wooden—building The sanatorium is erected at Ratcher Hill in Sherwood Forest, near Mansfield, upon an elevated site consisting of 50 acres of land presented by the Duke of Portland The soil is gravel and the sanatorium stands in grounds which are covered with pine trees and heather and from which an admirable view of the surrounding country is obtained The cost of erection, furnishing, lighting, sewering, water supply, &c, slightly exceeded £6000 and this sum was provided solely by voluntary subscription Among the public bodies subscribing were the corporation of Nottingham (£1000) and the town council of Mansfield (£200)

The building itself is a wooden structure erected upon a brick base and having a galvanised iron roof The central portion of the structure, which has two storeys, is devoted to administrative purposes and is of such dimensions as to afford accommodation for a larger number of patients than the institution at present contains Running out from each side of this administrative centre is a wing for the accommodation of patients, one wing for males and the other for females There is a small single ward in connexion with each wing and on either side of the main wards is a glass-roofed verandah, closed at either end and open in front, which acts as a *Liegehalle* and in which certain of the patients sleep during the night. In the grounds close to the sanatorium are two single shelters for male patients

The detai
better class
structured of
an air space
as to afford
tion is provided for by windows and in the roofs of each large ward are two extraction shafts Lighting is by means of electric light generated upon the site and warming by means of low-pressure pipes arranged in the form of radiators The lavatories are disconnected from the wards and the sewage is conveyed to a distance and treated on biological lines The

TABLE II —GIVING PARTICULARS OF 30 CASES OF CONSUMPTION TREATED IN WESTMORLAND SANATORIUM IN WHICH THE DISEASE WAS SLIGHT

Consolidation barely detectable, tubercle bacilli rarely found, no high fever

Case	Sex	Weeks in sanatorium	Weight gained in pounds	Bacilli	Previous illness	State on admission	Months since discharge	History after discharge
1	M	8 2	7	Not found	2 months	Both lungs slightly affected	30	Full farm work 2½ years

county council did not feel itself able to accept a certain provisional offer on the part of the owner of the property. The county council, however, voted £300 towards the expenditure necessary. Since the estate has been taken over two substantially constructed electric-lighted shelters, one for eight males and the other for eight females, have been erected out of moneys provided by public subscription The patients are admitted by a medical board comprising four medical men and one layman and the current expenses are furnished by public subscription and by the contributions from employers and bodies of workmen. An annual subscription of £75 gives the right to nominate suitable patients to one bed for a year and the King's Norton board of guardians is among those which thus secure a bed. A few paying patients are admitted at a charge of 30*s.* per week. There are a resident medical officer and a complete staff.

I must in passing make reference to the experiment which is being made at Clare, in Suffolk, through the efforts of Dr. Jane Walker who has rented a cottage in that village for the purpose of providing accommodation for those who are unable to pay even the low weekly sum of from two to three guineas demanded by the more humble sanatoriums. Dr. Walker has, I understand, found that a charge of 15*s.* per week, exclusive of washing, is sufficient to pay all expenses save the cost of rental, which in this case is a relatively insignificant sum. I was glad, therefore, to learn when visiting the East Anglian Sanatorium at Nayland that Dr. Walker hopes to be able to provide accommodation for a certain number of less well-to-do consumptives upon a remote portion of that truly admirable site and under conditions which will in no sense interfere with the privacy of the present sanatorium.

It is impossible to state at all accurately the number of sanatoriums which at present exist in the British Isles because in the first place it is difficult to decide upon what basis the computation is to be made, and in the second because there is no system of compulsory registration of such institutions in force.

But, excluding Poor-law institutions and including hospitals for consumption and homes for the dying, there would appear to be, approximately speaking, about 60 institutions, public or private, at which cases of pulmonary tuberculosis may be accommodated. The number of beds which are embraced by these institutions is probably under 2500 and assuming each bed to be occupied for three months there may be in England and Wales, Ireland and Scotland, some 10,000 beds available annually. If to this number the accommodation available at workhouses and infirmaries be added the total must be very materially augmented.

Now I cannot pretend to take part in the discussion as to the relative values *quâ* cure of large and small establishments. The matter is doubtless one of importance, but I hope I shall be forgiven if I venture to suggest that it is subordinate to the main issue, and it is the main issue which in this vast problem of tuberculosis we must, I think, be careful to keep before our eyes.

So far as I can judge, the main object in the provision of sanatoriums is to secure means whereby the tuberculous patient may be taken out of the environment in which he either contracted or developed his illness and to put him under conditions in which he may cease to furnish hospitality to the tubercle bacillus. The most important factors in promoting this alteration of tissue are an abundant supply of suitable food, rest, fresh air, light, and freedom from anxiety. These essentials can be provided almost as well in a small, suitably constructed establishment as in a large three-storeyed institution, the adequate ventilation of which is somewhat difficult of attainment, and hence I question the desirability of waiting until a marble palace can be provided and in the meantime allowing an uncertain number of people to die whose lives might otherwise be prolonged. Obviously, a suitable site must be procured, but much of this is a very relative matter; some sites are altogether unsuitable, but between the best and the second best the rate of recovery among the patients is not perhaps so very great. I am reminded by an admirable address by Dr. William Robinson of Sunderland that Dr. Léon Petit once said: "In all sanatoriums, whatever their geographical position, the curative results obtained are nearly the same, provided that the hygienic method is applied there in all its scientific rigour." It is for this reason that in the short sketch I have given of the subject I have dwelt upon the more humble accommodation which is at present being made in several parts of the country.

Homes for advanced consumptives.—Looked at from a purely preventive standpoint there is obviously far more importance to be attached to the control of cases which are likely, owing to their domestic environment, to be some danger to the community than there is to be attached to those cases which are in the earlier stages of the disease but who are expectorating little, if at all.

Although we may not altogether agree with Professor Koch that the action hitherto taken in this country in the direction of isolation has been the important factor which he supposes in bringing about the diminution of the disease, we must, I think, recognise the utility of providing accommodation for such cases as appear from their environment to be a source of special danger. In saying this I do not wish to lose sight of the proportions of the issue or to suggest for one moment that there shall be anything approaching compulsory isolation even for advanced cases. My point is simply this: that accommodation for advanced cases housed under obviously unwholesome and, for their relatives, dangerous conditions would be desirable. This aspect of the question has been recently faced in a practical fashion by the Westmorland county council, and Dr. Rushton Parker has written a highly suggestive paper upon the subject. I will draw attention to a few of his more important points, as they bring out the practicability of schemes of this nature and present the matter in a very concrete form. Dr. Parker thinks that about 35 out of the 50 or 60 deaths which occur annually in Westmorland from tuberculosis might, were there an institution for advanced cases, die therein. He thinks that a home with 20 beds would suffice for 40 cases remaining six months each and he calculates the total cost per annum to be about £1300, or £65 a bed. About one-sixth of the cases would, he thinks, be chargeable to the guardians. The county council has, he states, legal power to provide such a home and the cost thereof would be covered by a penny rate. He points out that the 8000 consumptives in the English workhouse infirmaries cost £600,000 a year, or £75 per head.

I regret that time will not enable me to refer to the work which is being done in connexion with towns such as Manchester, Liverpool, and Leeds, but I shall hope at a later date to say something as to this.

In bringing these lectures to a close it is perhaps hardly necessary for me to add that all those who are engaged in this endeavour to lighten the burden of tuberculosis upon the human species have my very fullest sympathy. My object in examining the problem somewhat critically has been to prevent, if possible, the reaction which I fear is inevitable unless the more extreme views are a little toned down and prophecies as to the early extinction of the disease through the agency of sanatoriums alone are less freely indulged in. It is the obvious duty, as it is clearly the desire, of all to heal the tuberculous sick and to protect the weakly against the disease. As to this all who face the matter seriously are in agreement. Our differences are merely as to the degree of communicability of the malady and as to the relative importance of each of the factors proposed to hasten the continued decline of the disease.

If I were told to select three, and three only, of the agencies with which I have in some degree dealt in these lectures as those upon which, assuming always a sufficiency of food, I would place most reliance as regards the control of pulmonary tuberculosis, I should arrange them somewhat in this order. 1. The education of older children in the principles of health, and the periodical physical examination of all school children with a view to improving the health of those prone to tuberculosis or who may already be suffering from the disease in an unrecognised though not unrecognisable form. The direct and indirect results which would accrue from this would soon make themselves felt in the direction of an unwillingness on the part of the people to occupy slums or to dwell in places where the sun rarely penetrates. It would also result later in a return to local and perhaps central administrative bodies of representatives who were more alive to the importance of the public health aspect of their duties than is always the case at the present time. 2. Some such system of compulsory insurance against sickness and invalidity as obtains in Germany and which, it is important to note, makes for the provision of sanatoriums, the support of those threatened with illness, and the general well-being of the poorer classes. 3. Better housing and improved conditions of employment of the working-classes—i.e., more light, more air-space, better ventilation, and greater cleanliness in the home, the workshop, and the factory.

And now, in conclusion, may I, Mr. President and Fellows, thank you once more for the honour you have done me in appointing me to deliver these lectures and may I also express my great appreciation of the attention with which you have been good enough to follow my efforts to examine dispassionately certain aspects of this absorbing problem.

A Lecture

ON

INFANTILE SCURVY.

Delivered at the Medical Graduates' College and Polyclinic

BY W. S. COLMAN, M.D., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO ST. THOMAS'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LADIES AND GENTLEMEN,—Infantile scurvy is a disease which has only received recognition during the last 30 years. Owing to the growing practice of bringing children up "on the bottle" cases are encountered with increasing frequency. It was mainly at the Hospital for Sick Children, Great Ormond-street, that its nature was first recognised by Dr. W. B. Cheadle and its natural history, pathology, and symptomatology were completely worked out by Sir Thomas Barlow. It is true that isolated cases of the condition had been previously met with, but except in one case recorded by [illegible] The first [illegible] 1876 by Sir [illegible] mond-street [illegible] f the long [illegible] ture of the [illegible] published Three Cases of Scurvy supervening on Rickets in Young Children[2] and insisted on its identity with the scurvy of adults. In 1881 Gee published, in the St. Bartholomew's Hospital Reports, a series of cases under the name of Osteal or Periosteal Cachexia and in 1882 Cheadle again maintained the scorbutic nature of the affection in a second paper on Osteal or Periosteal Cachexia and Scurvy.[3] Cases were also published in Germany under the title of Acute Rickets. But while the credit of pointing out the nature of the affection belongs to Cheadle, it was a remarkable paper read by Barlow in 1883 before the Royal Medical and Chirurgical Society which secured general recognition of Cheadle's views. This paper was entitled "On Cases described as Acute Rickets which are probably a Combination of Scurvy and Rickets, the Scurvy being an Essential and the Rickets a Variable Element." Illustrative clinical cases were minutely described, together with an exhaustive analysis of the post-mortem [illegible] (one being the case published [illegible] The original paper should be [illegible] the subject; it is a model of observation, description, and accurate reasoning and so complete that little has been added to our knowledge since and scarcely a line would require any modification to-day. After the publication of this paper the essentially scorbutic nature of the affection quickly gained general recognition and at the present time it is known in France and Germany as "Barlow's disease." The name "acute rickets" died hard and was followed in this country by "scurvy rickets." At the present time, however, Barlow's contention that rickets is an accidental association and is not invariably present has gained general acceptance and the term "infantile scurvy" is more frequently and appropriately employed. During the last 20 years many cases have been published. Barlow himself took up the subject in the Bradshaw lecture delivered by him at the Royal College of Physicians of London in 1894 and Cheadle summed up our knowledge in an admirable article in Allbutt's "System of Medicine," vol. v., in 1898. There is yet, however, much left obscure in connexion with the way in which scurvy is brought about, although we know that one constant factor is the absence of sufficient quantity of certain kinds of fresh vegetable or animal food. These matters will be more fully discussed later.

Symptoms.—The clinical picture presented by a child suffering from severe scurvy is so characteristic that anyone conversant with the disease can usually recognise it at a glance. The child usually shows no emaciation and, in fact, is usually well supplied with subcutaneous fat. The face is pale and in the later stages has a peculiarly earthy tint. He may be lying quietly in his cot without any obvious discomfort, but if anyone approaches the cot he screams with apprehension and if moved in any way gives a peculiarly piercing shriek of pain. If the bedclothes are removed the attitude of the child is also characteristic. Although he may be screaming and furious at the medical man's approach he does not kick his legs about as a child in a temper naturally would, but the lower limbs lie quite still, everted, with the thighs abducted and the knees a little flexed. When the legs are gently handled there is very marked want of tone of both skin and muscles, as well as actual feebleness of the muscles. The bones of the limbs are tender and usually there are local swellings due to subperiosteal hæmorrhages, most frequent just above or below the knee. At the site of these swellings the tenderness is extremely acute and the skin is often tense and glossy. On handling the limb soft crepitus may be elicited, fracture having taken place at or near the epiphyseal line. The arms are as a rule less tender, but they may be the only site of hæmorrhage, which is most frequent near the upper end of the humerus. There is occasionally hæmorrhage from the periosteum lining the orbit, giving rise to proptosis and ecchymosis of the eyelids. An excellent coloured illustration of this condition is given by Cheadle in Allbutt's "System of Medicine."

Changes in the gums.—If no teeth have been erupted changes in the gums may be absent or limited to an ecchymosis over the site of the incisors. Similarly it has been noticed in scorbutic adults that the gums are not spongy at all if the patients are edentulous. When any teeth have been cut there are nearly always changes in the gums, although one or two cases have been recorded in which the gums were healthy. In very mild cases there may be merely slight swelling and hyperæmia, but in marked cases the hyperæmic gum becomes purple from extravasated blood and the edge of the gum swells up so that the teeth may be almost concealed in a dark fungating mass which bleeds at the least touch. The gums readily ulcerate and sloughs form which disengage a disgusting "carrion-like" odour. This condition of the gums was also a prominent condition in adult scurvy. Joinville, in his history of the Crusade under Louis IX. (in connexion with an outbreak of scurvy outside Alexandria), writes: "The barbers were obliged to cut away very large pieces of flesh from the gums to enable their patients to eat. It was pitiful to hear the cries and groans of those on whom the operation was being performed; they seemed like the cries of women in labour." The rapidity with which these spongy gums subside when the patient is placed on a proper diet is as striking as the recovery of the periosteal lesions.

Of other scorbutic symptoms epistaxis and hæmaturia are not uncommon and lead to increase of the anæmia, but are not usually severe. Petechiæ and subcutaneous echymoses, so common in adult scurvy, are only of occasional occurrence in the infantile form.

Mild cases.—You must not always expect to meet with the symptoms as fully developed in all cases, especially in the early stage. Cases occur, for instance, in which

---

[2] THE LANCET, Nov. 16th, 1878, p. 685.

[3] THE LANCET, July 15th, 1882, p. 48.

the only symptoms are fretfulness and sponginess of the gums; in others, tenderness of the limbs on active or passive movement without any periosteal swellings, and occasionally hæmaturia may be the only symptom. I may mention three cases of this latter class. A well-developed boy, aged ten months, had had a diet consisting only of sterilised milk for four months. He then began to pass considerable quantity of blood in the urine and a diagnosis of renal sarcoma had been made. As soon as fresh milk and orange-juice were substituted for the sterilised milk the hæmaturia disappeared and the child has grown up perfectly healthy. In a second case a boy, aged 13 months, had been fed almost exclusively on a malted food. He had hæmaturia with practically no bone tenderness. He had his eight incisors and the gums over them were quite healthy but there was distinct sponginess over the site of the future first premolars. In the third child, aged eight months, there were hæmaturia and general tenderness without swelling. The blood was bright red. The child died suddenly from some unexplained reason the day after admission. The kidneys and bladder appeared healthy, but there was a submucous ecchymosis, probably scorbutic, in the membranous part of the urethra.

Association with rickets.—As would be expected, the dietetic errors which cause scurvy also predispose to rickets, so that the two conditions are often present together, but scurvy may be met with where there is no sign of rickets, just as rickets is often met with alone. In consequence of the frequent association of rickets there may be catarrhal troubles of the respiratory and alimentary tract due to the latter condition, but scurvy alone rarely causes any lung complications and except for the trouble in the gums scarcely ever sets up any disturbance in the alimentary canal. In fact, the appetite is usually large, although there may be some difficulty in administering food owing to the tenderness of the gums. And it is fortunate that the relish for food is so well preserved since when antiscorbutic articles of food are given the large quantities which the child is willing to take materially hasten the cure. It will be noticed that the parts attacked by the disorder are those which are in a state of great functional activity at the time of life when scurvy appears—the epiphyseal region of the long bones and the gums in the neighbourhood of the recently cut teeth. There are two other positions in which bone lesions have been observed in a few cases. The ribs near the costo-chondral junction may be affected and there may be separation of the ribs from the cartilages. In a case mentioned by Barlow "the sternum, with the accompanying cartilages, seemed to have sunk bodily back as though it had been subjected to some violence which had fractured several ribs in front and driven them back." Another exceptional position is the cerebral dura mater, where large hæmatomata have been described by Sutherland[4] and others.

Morbid anatomy of the bone lesions.—If a vertical section is made through the femur in a well-marked case the following conditions are observed. 1. Hæmorrhage beneath the periosteum, raising it and leaving the shaft bare, sometimes over its whole extent. If the periosteum is examined microscopically it is found to be thickened and broken up by numerous hæmorrhages. There are, however, few signs of inflammation. As a rule no new bone is formed on this elevated periosteum and in the rare cases in which such formation occurs the new bone is soft and small in amount and the shaft rarely, if ever, necroses, as in cases of infective periostitis. 2. Although necrosis is not to be feared the nutrition of the shaft is interfered with and fractures are frequent. These are usually seen at the epiphyseal junction or a little way from it. Crepitus is *soft*, partly from the effused blood-clot. When fracture occurs at the lower end of the femur blood may fill the knee-joint. 3. There are changes in the internal structure of the bone—rapid rarefaction of the cancellous tissue of the bone and hæmorrhages into the centre of the shaft.

Diagnosis.—When the condition is well developed the diagnosis is usually easy, particularly when the gums are spongy, but in the early stage or in slight cases it is often difficult. But if there is any bone tenderness which cannot be accounted for it is always wise to anticipate any possible scorbutic developments by giving fresh, unsophisticated milk and some suitable vegetable food. The conditions with which it is most likely to be confounded are: 1. Periostitis. In scurvy the temperature is rarely high, 100° or 101° F. being usually the highest, and often it may be normal or subnormal. The pyrexia in periostitis in young children is usually severe. In many cases the spongy gums or the presence of similar swellings on other bones will make the diagnosis clear. 2. Syphilitic epiphysitis. Although the state of the limbs in the two conditions is often similar they attack children at different ages, the syphilitic cases being nearly always under six months of age, while scurvy is almost invariably met with after that age. Further, the nutrition of the syphilitic cases is usually poor, while the scorbutic cases are nearly always well supplied with fat. 3. Paraplegia or infantile paralysis. This is suggested by the immobility of the limbs as well as by the extremely soft and atonic condition of the muscles. As most of the children are rickety there is often a curvature in the dorso-lumbar region of the spine which may be mistaken for caries and so suggest that the child's refusal to move the limbs is due to pressure on the cord. The bone tenderness, the spongy gums, and other signs of scurvy quickly enable any paralytic cause to be set aside. 4. Ordinary ulcerative stomatitis. In scurvy the changes are confined to the gums and are not found on the tongue and cheeks, as in ulcerative stomatitis.

Treatment.—This consists solely in rectification of the diet. Fresh, unboiled milk must be given instead of sterilised milk, all desiccated infants' food must be given up, and fresh vegetable or animal food must be given. Owing to the good appetite of most of the patients it is usually easy to get them to take large quantities of food. In addition to fresh milk and cream, potato soup may be given. This may be made by cooking a small potato in its jacket, sieving it, and then pouring over it a breakfast-cupful of boiling milk and adding a little sugar if the child likes it sweet. If the child will not take potato soup some broth may be given in which a muslin bag of chopped-up potato, carrot, &c., has been suspended while the broth was being made. Raw meat juice may also be given. Four ounces of steak meat should be scraped or finely minced, placed in a saucer, and just covered with cold water in which a pinch of salt has been dissolved. After standing for half an hour the juice should be expressed through muslin. Orange or lemon juice suitably sweetened should also be given. The limbs should be placed between sand-bags to keep them from being moved or, in the case of the arm, the hand and forearm may be gently bandaged to the side. If the diet be rectified both pain and swelling almost instantly subside and sedatives are rarely required. Any treatment of accompanying rickets may be postponed. As Cheadle points out, cream at such a time is better than cod-liver oil and raw meat juice is better than iron.

So far we have been on firm ground of observation, but when we come to consider the etiology of scurvy we find that there are many gaps in our knowledge and that many of our conclusions must be regarded as provisional only. It is, however, certain that the disease is clinically and pathologically identical with scurvy in adults and that the most important, though probably not the only, factor is the absence of sufficient *fresh* animal or vegetable food from the diet. It may be well briefly to review the evidence of this in the case of adult scurvy which was such a scourge both on land and sea to our forefathers.

1. The most familiar proof is furnished from the history of scurvy occurring on board ship. When ships had been some time at sea and fresh vegetables were not procurable scurvy frequently broke out. The narratives of Columbus and the early explorers frequently tell of ships scarcely able to reach port because there were not enough hands free from scurvy to work the ship. Immediately, however, that they touched land and were able to procure abundance of fresh food even the worst cases quickly recovered. In both merchant ships and in the navy until recent times scurvy was terribly frequent until it was found that the juice of fruits would also prevent the occurrence of scurvy; but from the time that it was made compulsory for lime juice to be carried and for all hands to take a sufficient daily dose of it scurvy soon became a rare disease at sea. No doubt the disappearance of scurvy has been hastened by the employment of steam, so that vessels call at ports at shorter intervals and so do not run short of vegetables and fruit. Modern steamers also now have arrangements for storing large provisions of vegetables and meat in cold chambers.

2. It has been noticed again and again in the case of armies in the field that in winter, unless efficient commissariat arrangements were made for providing fresh vegetables, &c., scurvy would break out, but that the epidemic

---

[4] Brain, 1894, p. 27.

would subside when, on the advent of spring, fresh vegetables were once more procurable Instances of this occurred during the Crusades, and the following instance which occurred in Chitral as lately as 1885 may be quoted It was related by Lieutenant-Colonel H Hamilton, I M S, in the *British Medical Journal* of Oct 25th, 1902. "In the year 1885 I was in medical charge of the 23rd Pioneers in the Hurnai Pass Knowing that no fresh vegetables would be procurable I had arranged that a native dealer should open a shop and get up supplies from India One day a man came to hospital with an obscure swelling of the leg which suggested scurvy and I said, 'You have not been eating vegetables' To this the man replied that there were none to be got, in short, the native dealer had found it so difficult to supply vegetables that he had given up the attempt I then examined some of the sepoys and followers and found in nearly every case that the gums were showing signs of scurvy Looking round the barren hill sides I found a little cruciferous plant This I showed to a native officer who said he knew it well and it was rank poison. I said, 'That may be, but we officers are going to have a spinach made of it and we are going to eat it in the mess to night' On my return to camp the same native officer met me and said he had in the meantime boiled and made into spinach some of the plant and that it was very good. The result of my trial of it was that I had a regimental order published stating that this plant was good to eat and that anyone found with scurvy would be punished During the rest of our stay there, which extended to several months, I sent out two men per company daily to collect herbs, which after inspection by me were cooked for the companies The result of this was that we had no more scurvy'

3 During sieges, when the supply of fresh vegetables and animal food runs short, scurvy usually breaks out, as in the siege of Paris in 1870, where it was very prevalent. "In 1703, during the siege of Thorn in Prussia, by the Swedes, which lasted only five months, 5000 of the garrison, besides a great number of the inhabitants, died of it The besiegers were at the same time quite free from it" (Budd)

4 Scurvy is also frequent in northern latitudes where vegetation disappears during the severe winter and this has caused a heavy death roll among Arctic explorers But as Nansen has shown, the absence of fresh vegetables may be compensated for by taking an abundance of fresh meat The Esquimaux, who are great meat eaters, usually escape, and during his long journey towards the North Pole Nansen made his men eat large quantities of fresh meat and had not a single case of scurvy among members of his expedition Another example showing the efficacy of fresh animal food is give [illegible] zen Land," p 99 [illegible] t Habarova, North [illegible] Russian monks and one lad who acted as their general servant They belonged to the strictest sect of the Russian priesthood and were bound by their vows to abstain altogether from meat This obligation did not apply to the lad who was kept busy and in constant exercise and lived on fresh reindeer meat At the end of the second winter (in May) the Russian peasant traders and Samoyads came back from the Pechora to find all the six priests dead of scurvy and the boy of 12 in perfect health"

5 Land scurvy was endemic in many parts of England a few centuries ago, probably owing to the circumstance that "till the commencement of the sixteenth century no salads, carrots, or other edible roots were grown in England The little of these vegetables that was used before that time was imported from Holland and Flanders and in the reign of Henry VIII Queen Catherine, when she wanted a salad, was obliged to despatch a messenger thither on purpose' (Budd) Potatoes had not been introduced into England at the time when scurvy was prevalent What is true of large masses of population has also been exemplified in individuals, and even in this country cases of scurvy are occasionally met with in adults and older children In the case of the latter it is nearly always found that they are children who dislike fresh vegetables and have been allowed to go without them I remember a woman being admitted into the ward with scurvy when I was a student She lived in a garret and subsisted almost entirely on tea, stale bread, and kippers

In all these cases, however, there has been not only deprivation of fresh food, but the food that they did get was probably greatly deteriorated in quality and this possible factor must be kept in mind It is curious that in cases of starvation due to privation, to disease, or to fasting for public exhibition, scurvy, as Osler has remarked, is practically unknown.

Returning to infantile scurvy we find almost invariably that there has been absence of a sufficiency of fresh milk and in most cases the administration of preparations of milk in which the composition of the milk has undergone some more or less profound alteration The antiscorbutic properties of fresh milk are slight but sufficient. No case has yet been recorded in which a breast fed child developed scurvy (except during epidemics when the mother was herself scorbutic) and it can also be avoided by keeping a child on a sufficiency of fresh cows' milk When the actual feeding of a series of infantile scurvy is investigated two facts are at once evident. (1) that in none of them is the child taking a diet solely of fresh milk and (2) that the great majority are being fed on milk sterilised at high temperatures or on patent foods containing milk which has been desiccated Both these propositions are so well established that I need not detain you by marshalling statistics in their support, merely pointing out that the chief factor in infantile, as in adult scurvy is the absence of sufficient fresh "living" food and that if a proper amount of "living" food is administered scurvy can not only be prevented but, if present, can be cured But there are one or two problems which still await solution in connexion with scurvy and I propose to touch on two of them

1 How does fresh food prevent and cure scurvy? Is it owing to the presence of some definite body or bodies or is it through some property inherent in fresh food which we cannot at present define? The presence of some definite body is the most convenient supposition and it is spoken of as glibly as we speak of the hypothetical ether which is assumed to pervade the universe and there are many considerations which give it support Most antiscorbutic plants are rich in potash and many of them in organic acids as well, as Sir Alfred B Garrod showed half a century ago, and he was inclined to attribute scurvy to the absence of organic salts of potash in the food And this seemed to be confirmed by the observations of Ralfe that in scurvy there was a marked diminution of the alkalinity of the blood But the administration of organic or other salts of potash in cases of scurvy has been without any effect. Nor has research in any other direction for some definite antiscorbutic body at present proved successful and there are one or two considerations which are opposed to the view that there is a single antiscorbutic substance Among these is the observation that some foods lose their antiscorbutic power when cooked, while others are unimpaired The antiscorbutic powers of milk [illegible] destroyed by prolonged boiling [illegible] meat are impaired by cooking, [illegible] effective in scurvy than beef tea is But potatoes and green vegetables seem to lose none of their virtue by being cooked I am afraid that we cannot yet get beyond Barlow's position that "*the problem is biological as well as chemical and that* the further we get from a living food the less is its antiscorbutic power'

2 Are there any positive factors in addition to the negative one which all admit? Many have been suggested and disproved For instance, it was once maintained that congenital syphilis was often an exciting cause This I am confident is erroneous Rickets, again has been held responsible The frequency with which rickets is associated lends support to the view But cases of infantile scurvy *have been recorded in which there was no sign of rickets so* that scurvy is not a manifestation of rickets although probably predisposed to by it The frequency with which rickets is present in scorbutic infants is mainly due to the improper diet in each case But we open a larger and more difficult question when we inquire whether there is not some positive morbific influence in connexion with the food the child has been taking It is probable that there is such a factor, though much less important and less constant than the absence of fresh food, and that this is probably due to the presence of bodies developed by alterations in the composition of the proteids in the milk, the result of predigestion, sterilisation, or desiccation as the case may be That there is such a factor is strongly suggested by the fact that infantile scurvy not infrequently occurs when children have been taking a fair quantity of fresh milk if they are taking at the same time one of the various patent dried foods or if the fresh milk has been pancreatised, and according to Cheadle scurvy is specially liable to develop where the patent foods have been partially predigested during their

manufacture. Out of 23 cases I have had the opportunity of investigating in hospital and private practice 19 were taking some kind of patent food as their staple diet and no fewer than seven of these were taking fresh milk at the time. The other four had been fed on sterilised or "humanised" milk. In Cheadle's "Lectures on the Practice of Medicine"[5] he gives full details of the previous food of 60 cases of scurvy. Of these, 46 were taking various patent foods, mostly "malted," and of these 13 were taking milk, said to be fresh, with the food. Of the remaining 14, three were taking peptonised milk and seven sterilised or "humanised" milk. Cheadle, however, attributes the scurvy not to the direct influence of the dried foods but to the quantity of milk taken being insufficient to act as an antiscorbutic.

It must be admitted that the case is not yet proved, but I may refer to a further suggestive point. Among the cases of scurvy that I have seen there were three in which the condition had been recognised and fresh milk and raw meat-juice added to the diet but in which the patent food which the children had been taking was not stopped. As a result of this partial change of diet there was only slight improvement, but at the end of some days the gums were still spongy, the swellings had not gone down, and the pains were still severe. In each case the only alteration suggested in the treatment was the complete abandoning of preserved food of any kind. The improvement was then as rapid as it usually is in children admitted to hospital and at once placed on a "living" diet. I cannot pretend that we have any knowledge of what poison or poisons could be responsible, but in the case of predigestion of milk it is well known that the process must not be carried on long or toxic bitter substances will be formed, and it is quite a feasible notion that other bodies may be developed from the proteids of the milk by the various modes of preparation which may favour the occurrence of hæmorrhagic lesions. If we turn to adult scurvy we find that where scurvy is epidemic, as in sieges, long voyages, &c., the quality of the provisions obtainable had usually deteriorated—meat having become tainted, flour mouldy, and so forth. And it is probable, I venture to think, that products of decomposition (not necessarily offensive) are subordinate factors, the essential one in both children and adults being the absence of sufficient fresh vegetable and animal food.

ON THE ACTION OF HÆMOLYTIC SERA.

By ROBERT MUIR, M.D., F.R.C.P. EDIN.,

PROFESSOR OF PATHOLOGY, UNIVERSITY OF GLASGOW; PATHOLOGIST TO THE GLASGOW WESTERN INFIRMARY.

It has been abundantly shown by researches within recent years that the destruction of red corpuscles and bacteria by their respective anti-sera takes place according to practically the same laws. The phenomena can, however, be more readily and more exactly studied in the case of hæmolysis, owing to the visible effect produced by the action of the serum; the facts thus ascertained can then be tested in the case of anti-bacterial sera The subject of hæmolytic sera is thus one of great practical importance. It is also one of the highest interest from the biological point of view, exemplifying, as it does, one of the most remarkable reactive powers which the animal body possesses.

It is unnecessary to give a historical survey of the subject, as this has recently been done in several excellent articles.[1] It will be advisable, however, to mention some of the fundamental facts established by the researches of Bordet, Ehrlich and Morgenroth, von Dungern, and others.

If an animal is injected with the red corpuscles of an animal of different species its serum acquires the power of dissolving such corpuscles and on repeated injections this hæmolytic power may attain a very high degree. (When a serum normally possesses a hæmolytic action this property, of course, becomes accentuated by the method indicated) In the hæmolytic action two substances are concerned, one being the comparatively stable substance which gives the serum its special character—the *immune-body* of Ehrlich—and the other being a substance present in normal serum, highly sensitive to heat and other agencies—the *complement* of Ehrlich. As was first shown by von Dungern, the immune-body alone increases in amount during the stages of immunisation, the complement remaining practically unaffected. Accordingly, in testing a hæmolytic serum, its complement is first destroyed by heating at 55° C. and varying amounts of the heated serum are used along with a sufficiency of fresh serum of a normal animal to supply the necessary complement; otherwise the full hæmolytic value of the serum would not be obtained. The term "immune-body" will be used for convenience as indicating the hæmolytic serum deprived of its complement by heating and the term "complement" as indicating the fresh serum of a normal animal. As regards the mechanism of hæmolysis, there are two chief theories—that of Ehrlich and that of Bordet. *According to the first*, the immune-body possesses two chief combining groups, one by which it becomes combined with the red cells—the cytophile group—and another by which it fixes the complement—the complementophile group; hence, Ehrlich has called the immune-body an amboceptor. The immune-body has, however, little or no affinity for complement until it has become attached to the red corpuscle. According to Bordet the immune-body sensitises or has a mordant-like action on the red corpuscles whereby they become susceptible to the action of complement (hence he uses the term "*substance sensibilisatrice*") and complement (or "alexine," as he calls it) combines directly with the sensitised molecules. The following research was carried out in order to study more closely than had been done the combining relationships of immune-body and of complement, and especially to inquire into the possibility of dissociating these substances, singly or together after they had combined. When I commenced my experiments there was practically nothing in literature on the latter subject, although certain results have since been published. The sera used in most of the experiments have been those of rabbits, immunised against the red corpuscles of the ox. The normal serum of the guinea pig has a distinct though slight hæmolytic action on the corpuscles of the ox owing to the presence of what we may call a natural immune-body (the *Zwischenkorper* of Ehrlich). This has little effect in the case of a single dose of complement but comes to be of importance when comparatively large amounts are employed. I have accordingly in all cases before using the complement placed the serum in contact with corpuscles of the ox at 0° C. for an hour, by which means all the natural immune-body becomes attached to the red corpuscles, while the complement remains in the serum, which is then separated again by centrifugalisation. I have used the corpuscles of 0 5 cubic centimetre of ox's blood (freed from serum) for each cubic centimetre of guinea-pig's serum and have found that 1·5 cubic centimetres of the serum thus treated have practically no effect on the test amount of the corpuscles of the ox In testing the value of immune body and complement I have used the methods of Ehrlich and von Dungern, the test amount of red corpuscles being one cubic centimetre of a 5 per cent. suspension of the corpuscles of the ox in 0·8 per cent. solution of chloride of sodium, the corpuscles being always freed from serum by repeated centrifugalisation and washing in salt solution.

Ehrlich and Morgenroth showed that red blood corpuscles might in certain instances take up many times the minimum hæmolytic dose of immune-body. This is of fundamental importance and, in fact, constitutes the basis of most of the experiments to be described. The immune body combines with certain molecules or receptors in the red corpuscles of the species of animal used; whether this is a true chemical combination or not need not be discussed at present. It will be convenient to use the letter R. as indicating the receptors which will take up the minimum hæmolytic dose (M. H D) of immune-body (I. B); thus when two hæmolytic doses of the latter are taken up the combination will be represented by 2 R. + 2 I B. I shall use the letter C. to represent complement; complete hæmolysis with minimum doses may then be conveniently represented by R. + I. B. + C

Before speaking of the separation of immune-body after combination it will be convenient to refer to some facts regarding the union of immune-body and red corpuscles. This union, as Ehrlich and Morgenroth showed in their first communication, takes place at 0° C., and thus a method is afforded for separating immune-body from complement when they are present together in a fluid. (This method, as already indicated, has been utilised for obtaining guinea-pig's serum practically free from natural immune-body and thus devoid of hæmolytic action on ox's corpuscles.) The amount of immune-body taken up by red corpuscles is usually tested in the following way. A number of tubes, each containing one cubic centimetre of 5 per cent. suspension of ox's corpuscles, are prepared and to these increasing multiples of the hæmolytic dose of immune-body are added in series—i.e., two doses, three doses, &c. *The tubes are then placed in the incubator for two hours at* 37° C., the contents being shaken well from time to time so as to allow time for complete combination. All the tubes are then centrifugalised and the contents of each are added to a fresh tube containing one cubic centimetre of suspension of red corpuscles, along with sufficient complement for hæmolysis. In this way we ascertain the smallest number of doses of immune-body which give a free dose of immune-body uncombined after the above treatment. In the case of rabbit's immune-serum I have found that the number of doses taken up by ox's corpuscles varies from six to ten; it is usually seven or eight (variation seems to depend both upon the serum in question and also upon the corpuscles used in testing). But it is to be noted that the union of immune-body and red corpuscles is not like ordinary chemical union, say of an acid and a base. If, for example, eight hæmolytic doses of immune-body are the smallest amount which gives one free hæmolytic dose we do not find that all the immune-body in the tube containing seven doses has been taken up; on the contrary, in this tube there may be almost a dose free, in the six-dose tube a *considerable amount, in the five-dose tube a trace, &c.* And evidence is brought forward below, that when there is a great excess *of immune-body present more is taken up than the* maximum brought out by this method of testing. It is therefore evident that the amount of immune-body taken up varies to a certain extent with the amount present.

---

[5] Smith,

[1] I may mention Aschoff [illegible] Jena, 1902; Sachs · Die Haemolysin [illegible] sch and Oestertag's Ergebnisse der Al [illegible] Recent Views on Immunity, Journal of Hygiene, 1902; Welch's Huxley Lecture, THE LANCET, Oct. 11th, 1902 p. 977; and Grunbaum's Goulstonian Lectures, THE LANCET, March 21st, 1903, p. 775, &c.; and von Dungern . Die Antikorper, Jena, 1903.

ON DISSOCIATION OF IMMUNE-BODY FROM RED CORPUSCLES.

In examining the possibility of separating immune-body after combination I took advantage of the fact that the red corpuscles of the ox take up several doses of the immune-body of the rabbit. The method then is to bring red corpuscles saturated with immune-body into contact with untreated corpuscles for a certain length of time and then to observe how much hæmolysis takes place when sufficient complement is added to the mixture. The details are as follows:—

. suspension of ox's corpuscles
une-body from the rabbit, for

corpuscles into contact. This tube is placed in the incubator for an hour. 4 The contents of Tube A are then shaken up and 0 2 cubic
added. At the same
h corpuscles is added
centimetre of comple-
37° C.

The result is that hæmolysis of all the corpuscles takes place in Tube A, whilst in Tube B the added corpuscles remain practically intact. This result has been recently published by Morgenroth,[2] but I may state that I obtained it quite independently and demonstrated the fact to several friends last November. *The only difference in the methods* used is that Morgenroth simply mixed the treated and untreated corpuscles in suspension, whereas I brought them together by centrifugalisation. The transference of immune-body to the untreated corpuscles takes place rather more quickly by the latter method. I have found that red corpuscles treated with 12 hæmolytic doses of immune-body will usually give up two hæmolytic doses to fresh corpuscles after contact for an hour at 37° C.—i.e., two cubic centimetres [illegible] experiment, will [illegible] *of sufficient co*[illegible] immune-body can [illegible] six hæmolytic doses. Dissociation takes place, though much more slowly, at the temperature of the room, while at 0° C. it is practically *nil*.

The explanation of the above result is quite clear and has already been indicated. In Tube A the untreated corpuscles have obtained by dissociation a hæmolytic dose of immune-body and the added complement is distributed over all. In Tube B the complement becomes fixed to the treated corpuscles before sufficient immune-body can pass to the untreated corpuscles; as a matter of fact, immune-body does pass over, but by the time this has occurred all the complement has been fixed. To explain the result in accordance with Ehrlich's theory as to the immune-body being an amboceptor, Morgenroth states that the combination of immune-body and red corpuscle becomes firmer when the former takes up complement—in other words, immune-body *is locked up by complement. If this were not so we would* expect immune-body and complement together to pass over to the untreated corpuscles. He, however, brings forward no direct evidence in support of this statement and, as will be shown below, it is possible to dissociate immune-body even when great excess of complement has been added. Experiments such as the above do not in themselves give any information as to the condition of immune-body after complement has been taken up. The question will be discussed again below.

ON THE CONDITION OF IMMUNE-BODY AFTER HÆMOLYSIS.

Supposing that red corpuscles containing several hæmolytic doses of immune-body are hæmolysed by the minimum amount of complement, we have to inquire in what state the surplus molecules of immune-body are. There may be said to be three possibilities: (1) the surplus molecules of immune-body may be destroyed in the process of hæmolysis; (2) they may become free in the fluid; or (3) they may remain in union with the receptors of the red corpuscles. It is easy to show in the first place that they are not destroyed, as abundant immune-body can be obtained from the red fluid resulting *from the hæmolytic action.*

ment they undergo complete hæmolysis.

As mentioned above, *free* immune-body unites with red corpuscles at 0° C. We may accordingly test whether immune-body is recoverable from the red fluid at this temperature. The steps are the same as in the above experiment, only after hæmolysis has occurred at Stage 2 the tube is placed in a mixture of ice and water, the fresh corpuscles are then added, and the mixture is allowed to remain at 0° C. for an hour. *Afterwards the tube is centrifugalised* and the corpuscles are washed in cold salt solution. Complement is then added to the corpuscles and the tube is placed in the incubator. The result is that there is practically no lysis, though a control with red corpuscles added to fluid containing a dose of immune-body at 0° C. and then centrifugalised, gives complete hæmolysis on the addition of complement.

We may therefore conclude that when red corpuscles containing several doses of immune-body are hæmolysed by the minimum dose of complement, the surplus molecules of immune-body do not become free but remain attached to the receptors of the corpuscles; a certain amount can, however, be dissociated at the higher temperatures on the addition of fresh corpuscles.

ON THE DIRECT UNION OF COMPLEMENT WITH CELLS.

In some preliminary observations on the behaviour of complement I found that it united directly with various animal and vegetable cells, a fact which I afterwards found had been recorded by von Dungern,[3] a considerable time previously. Of such cells may be mentioned those of the various organs *of the same animal as that supplying the complement* or of animals of different species, various bacteria, yeasts, &c. Von Dungern supposes that this combination takes place through the complementophile group of the amboceptors when they are still in position of side-chains in the cells. Whether this is the explanation or not need not be discussed at present; the important point is that molecules with direct affinity for the same complement are very widespread in the animal and vegetable kingdom. It is generally stated that red corpuscles, unlike other cells, have no affinity for complement, and it is the case that no

---

[2] Morgenroth: Münchener Medicinische Wochenschrift, 1903, No. 2.

[3] Von Dungern: Munchener Medicinische Wochenschrift, 1900, No. 20.

[illegible] that complement is not separable (nor I. B. + C.), the saturation with complement should lead to the locking-up of the immune-body molecules so that they can no longer be separated. Various experiments have been carried out in order to test whether this is the case. We may first take the case of red corpuscles which have been saturated with immune-body, the excess of immune-body having been completely removed by repeated centrifugalisation and washing. Suppose that the number of hæmolytic doses taken up is nine, then complete saturation will be represented by 9 R. + 9 I. B. + 9 C. If then we add another dose of C. we would expect to get free complement but no immune-body. This, however, is not the case. The following may be taken as an example.

1. Four tubes, A, B, C, D, each containing one cubic centimetre suspension of red corpuscles, are taken, and to each more than sufficient I. B. is added to saturate the corpuscles completely. The tubes are placed in the incubator for one and a half hours at 37° C. and then allowed to remain at the room temperature for another half hour. 2. They are then centrifugalised and washed with fresh salt solution, the process being repeated several times. 3. Complement is added—to A, 0·015 cubic centimetre; to B, 0·06 cubic centimetre; to C, 0·1 cubic centimetre; and to D, 0·2 cubic centimetre (M. H. D. of C. is 0·013 cubic centimetre). The tubes are placed in the incubator for two hours. Complete hæmolysis of course occurs in all. 4. One cubic centimetre of ·5 per cent. suspension of untreated red corpuscles is added to each and the tubes are placed in the incubator again for another hour.

The result is that the added corpuscles dissolve completely in D, while they remain intact in A, B, and C (there is possibly the slightest trace of hæmolysis in C). The corpuscles in the tubes A, B, and C are centrifugalised and washed in salt solution; 0·03 cubic centimetre of complement is added to each tube and the tubes are placed in the incubator. Complete hæmolysis then occurs in each tube. The explanation of this result manifestly is that in all the tubes sufficient immune-body was dissociated for complete hæmolysis, but that only in tube D was there a hæmolytic dose of free complement.

Objection might be made to using red corpuscles *saturated* with immune-body as some of the molecules might not have taken up complement. I have therefore compared the amounts of immune-body which can be dissociated from red corpuscles containing various doses of immune-body (1) before complement is added and (2) after complement is added. The following are the details. Nine tubes, each containing 0·5 cubic centimetre of 5 per cent. suspension of red corpuscles: to the first, two doses of immune-body are added; to the second, three doses; to the third, four doses; and so on up to ten doses. Two series of tubes, A and B, are thus prepared. If we take the 7 D. tube as an example, then in series A we have to find how much I. B. can be dissociated from 7 (R + I. B) and in Series B from 7 (R + I. B. + C.) + free C. Time is allowed for combination of immune-body and the corpuscles in each tube are then repeatedly centrifugalised and washed in salt solution. All the immune-body present is therefore in combination.

Series A.—To each tube after being treated as above is added 0·5 cubic centimetre of fresh corpuscles (5 per cent.). the tubes are shaken thoroughly, and then centrifugalised so as to bring the treated and untreated corpuscles into contact They are then placed in the incubator for an hour at 37° C. so as to allow dissociation to occur. The contents are then thoroughly shaken up and to each tube is added four hæmolytic doses of complement. The tubes are then placed in the incubator for an hour at 37° C. and the result is observed next day.

Series B.—To each tube complement is added in excess—i.e., much more than will be taken up by the treated corpuscles. To the tube with two doses of I. B., 0·2 cubic centimetre of C.; with three doses of I. B., 0·3 cubic centimetre of C.; and so on in increasing amount. The tubes are placed in the incubator for two hours so as to allow the maximum amount of complement to be taken up. To each tube is then added 0·5 cubic centimetre of untreated red corpuscles (5 per cent. suspension) and the tubes are placed in the incubator for another hour (During this time immune-body which can pass from the treated to the untreated corpuscles will do so, and, as there is plenty of free complement present, the latter will become hæmolysed in proportion to the amount of immune-body dissociated.) The tubes are placed in a cool chamber and the result is noted on the next day.

The following are the results obtained. The amount of hæmolysis of the added corpuscles in the two series practically corresponds. In the tubes containing originally from ten down to six doses (10 to 6 D.) of I. B. the added corpuscles have undergone complete lysis; in the tubes containing 5 D. almost complete lysis; in the tubes containing 4 D. distinct lysis; in the tubes containing 3 D. very slight lysis; and in the tubes containing 2 D. no appreciable lysis. It may therefore be concluded that from corpuscles combined with immune-body practically as much immune-body can be dissociated after complete saturation with complement as before any complement has been added.

We may also compare the amount of immune-body dissociated from red corpuscles containing multiple doses of immune-body under the two conditions: (*a*) when just enough complement to produce hæmolysis has been added and (*b*) after complete saturation with complement. If we take again the case where seven doses of immune-body have been added, then the two conditions to be compared may be represented as (*a*) (R + I. B. + C.) + 6 (R. + I. B.) and (*b*) 7 (R. + I. B. + C.) + free C. In both cases there is, of course, complete hæmolysis, but in the former case most of the I. B. is simply attached to the receptors of the red corpuscles, whereas in the latter all the affinities for complement have presumably been satisfied. The following are the details:—

Two series of nine tubes, each containing 0·5 cubic centimetre of red corpuscles, are prepared as before, and to the several tubes 2 D, 3 D., up to 10 D. of I.B. are added. Time is allowed for combination of I. B. and the corpuscles are centrifugalised and washed several times.

Series A.—Hæmolysis is produced by 0·03 cubic centimetre of complement, and after the tubes have been an hour in the incubator (and complete hæmolysis has occurred) there is added 0·5 cubic centimetre of red corpuscles (5 per cent.) to each tube. The tubes are then placed in the incubator for an hour to allow of dissociation of I. B. We then add sufficient complement—say, 0·2 cubic centimetre—which will produce hæmolysis in the added corpuscles, according to the amount of I. B. which they have taken up. The tubes are placed in the incubator for an hour at 37° C. and the result is observed next day.

Series B.—As in the previous experiment (*vide supra*, Series B) much more complement is added than the treated corpuscles will take up and an exposure for two hours at 37° C is allowed for combination. To each tube the standard amount of red corpuscles is added and the tubes are placed in the incubator for an hour, &c.

The result is that here also there is no perceptible difference between the two series. In the tubes from 8 D. to 10 D. there is complete lysis of the added corpuscles, in tube 7 D. almost complete lysis, in tube 6 D. much lysis, in tube 5 D. distinct lysis, in tube 4 D. a mere trace, and in tube 3 D. no perceptible lysis. In another experiment of the same kind one or two of the tubes in Series A showed slightly more lysis than in Series B but the difference was of quite a trifling nature. Here, again, the experiments described supply no indication of the locking up of the molecules of immune-body by the complement molecules. (It will be noted that in all these comparative experiments the time allowed for dissociation of I. B. and for its combination with the added corpuscles is one hour at 37° C. and subsequently about 15 hours at cool room temperature.)

Although, as stated above, I have found no evidence that the combination I. B. + C. ever becomes dissociated the objection might be made that in the experiments just described this may possibly occur. This objection can, however, be met by showing in a direct manner that the I. B. separates alone—i.e., without complement attached to it. The method is to super-saturate with complement a given amount of red corpuscles combined with immune body, then to remove the excess of complement present, and then to add fresh corpuscles and observe whether I. B. or I. B. + C. becomes dissociated. Bordet showed that an emulsion of a given bacterium, along with the corresponding anti-serum, can take up considerable quantities of hæmolytic complement, and for this purpose I have used the spirillum Mechnikovi along with its immune-body (heated homologous serum). The following are the details of such an experiment:—

1. Two cubic centimetres of 5 per cent. suspension of ox's corpuscles are saturated with I. B. and the corpuscles are then centrifugalised and washed several times so as to remove all free I. B. 2. 1·5 cubic centimetres of guinea-pig's complement are added and the mixture is placed in the incubator for two hours so as to allow complete combination of complement (hæmolysis of course occurs). 3. The red fluid is divided into two equal parts—A and B. 4. To A is added one cubic centimetre of red corpuscles treated previously with I. B. and the mixture is placed in the incubator. The result is complete hæmolysis. Therefore free C. is present in the fluid at [illegible] 5. To B is added 0·3 cubic centimetre of a fairly thick [illegible] spirillum and 0·2 cubic centimetre of th[illegible] mixture is placed in the incubator for an [illegible] remove free complement.) 6. One cubic [illegible] untreated red corpuscles is added to the fluid and allowed to [illegible] for an hour. The red corpuscles remain intact, therefore the free C. has been removed. 7. The corpuscles are then separated by centrifugalising and washed in salt solution and 0·1 cubic centimetre of complement is added. The result is that complete hæmolysis occurs. This shows that the fresh corpuscles obtained I. B. *alone*, otherwise they would have dissolved at Stage 6.

I have repeated this experiment with corpuscles combined with five doses of immune-body instead of being saturated. In this case the fresh corpuscles added at Stage 6 obtain almost a complete hæmolytic dose of immune-body. It is thus completely proved that the immune-body dissociated after complete saturation with complement comes off as I. B. alone and not in the combination I. B. + C.

Before considering the significance of the results obtained, it may be well to recapitulate the chief facts brought forward. These are: (1) each additional dose of immune-body *taken up by the red corpuscles leads to the taking up* of an additional and corresponding amount of complement (we may therefore infer that when red corpuscles containing 5 D. of I. B. are exposed to excess of complement, the I. B. molecules would really, according to Ehrlich's theory, become saturated with complement); (2) when such saturation has occurred I. B is still separable; and (3) the I. B. is separated without C attached to it.

The question is, what has become of the C. which was taken up through the medium of the I. B.? The natural assumption is that it has become united *directly* to the molecules of the red corpuscles. Certain other points will require to be settled before this is definitely affirmed, but it must be admitted that the above results—all of which have been confirmed—are opposed to Ehrlich's view as to the immune-body being a connecting link between complement and tissue molecules. The undoubted fact is that two substances in combination (tissue molecules + immune-body) take up an amount of complement which neither by itself will take up, and so far as I can see the above results cannot be reconciled with the view that complement becomes united to a complementophile group of the immune-body. Nevertheless I am fully aware that many other points will require to be cleared up before we gain a final conclusion regarding the relationships of these substances. It will, for example, have to be considered whether the facts brought forward by Neisser and Wechsberg[7] as to excess of immune-body interfering with the bactericidal action of complement can only be explained on the supposition that immune-body unites directly with complement.

SUMMARY OF CHIEF RESULTS.

1. Immune-body and complement differ markedly from each other in their mode of combination and in the firmness of union.
2. Immune-body can be in part separated before hæmolysis from red corpuscles containing multiple doses.
3. When red corpuscles containing multiple doses of immune-body are hæmolysed by the minimum dose of complement the surplus molecules of immune-body remain attached to the receptors of the red corpuscles and can be in part separated.
4. Complement after its union either directly with cells or indirectly through the medium of an immune-body cannot be separated again.
5. Each dose of immune-body taken up by red corpuscles in addition to the minimum hæmolytic dose leads to the taking up of an additional and corresponding amount of complement. In this way many times the amount of complement necessary for hæmolysis may be used up.
6. When red corpuscles containing multiple doses of immune-body are fully saturated with complement, immune-body can still be separated. The immune-body thus obtained comes off alone and not in the combination I. B. + C.

A portion of the work was done in the Pathological Department of the University of Oxford and I have pleasure in expressing my indebtedness and thanks to Dr. J. Ritchie for the excellent facilities there afforded me.

Glasgow.

A PROBLEM IN MEDICO-LEGAL PSYCHOLOGY.

BY J. S. MACKINTOSH, M.R.C.S. ENG., L.R.C.P. LOND.

THE Rev. ——, aged 34 years, when engaged one morning in making arrangements for a "treat" in connexion with his parish had occasion to make some short journeys on his bicycle to expedite matters. After the last of these bicycle runs he went up to his bedroom and was found not long after by his maid dead on the floor, with a wound in the head behind and a little above the ear, and a revolver on the floor beside him. The wound in the head was clearly self-inflicted. From the maid I learnt that the revolver was kept in the collar-and-cuff drawer (a point of importance in the case) as a protection from burglars. His wife was away for the night, having gone on a visit to her father on the previous day—a frequent occurrence. She was expected back every moment. The maid had not noticed any change *that day in her master's demeanour, he seemed in* excellent spirits, and she could not account in any way for her master taking his life. On proceeding with my examination I observed that a large piece of skin had been torn from the hypothenar eminence of the right hand as though by a fall. Being already aware that the deceased had been riding a bicycle that morning it occurred to me that he might have had an accident and seeking for confirmation I found hanging over the end of the bed a clergyman's cycling suit covered with mud all down the right side, a hole being torn in the knee. Correspondingly I found a large abrasion over the patella and a slight bruise on the right frontal region. It now became plain that the unfortunate man had had a bad fall from his bicycle, had gone home to change his clothes, and that during the process he had gone to his drawer, taken out the revolver, loaded it (for it was always kept unloaded and the box of cartridges was by his side), and shot himself.

Further examination showed that his toilette was complete except for his collar and cuffs. It was therefore a legitimate inference that he had gone to the drawer not for the revolver but for his linen, and that had the weapon been kept elsewhere the tragedy would in all probability not have occurred. The evidence given at the inquest and the result of my own inquiries both went to show that there was no reason discoverable that could have prompted him to contemplate self-destruction. His married life was most happy, his relations with his vicar were most cordial, and his finances were in order. He had no particular worries or troubles, as far as his friends and relatives knew; at no time had he shown a tendency to fits of depression; his family history was unsuggestive and no written word was left that could hint any reason for the act or even express intention. A witness of the fall was discovered. He saw the bicycle skid and the rider fall heavily on his right side, apparently striking his head. He tried to remount but, according to the witness, seemed unable to get into the saddle and desisting in the attempt proceeded to push his bicycle homewards.

From the foregoing facts I felt justified in drawing the following conclusions which I presented to the court in my evidence at the inquest. The effect of the fall was to induce that form of cerebral concussion which permits the sufferer to perform various complex and apparently reasoned acts of which he will retain no recollection when he has recovered from the effects of his concussion and which may be quite at variance with his usual behaviour, the mental condition being identical with that of the somnambulist, of the epileptic shortly after a fit, and of a certain phase of the hypnotic state. It was clear that the act was performed absolutely without premeditation from the evidence already given and from the fact that it was not until he had put on all but his collar and cuffs and had to go to the drawer where they were kept that he came across the revolver and made use of it. The sight of the revolver, its image impinging on the retina, started the ideo-motor sequence which ended in his loading the weapon, placing it to his head, and pulling the trigger, the act being automatic and not voluntary even as a sudden impulse, the deceased not being in reality conscious at the time.

Dr. J. F. Woodroffe of Harlesden, who had known the deceased for some years and had treated him professionally, gave evidence in support of my conclusions. He had arrived on the scene later in the morning after I had left and on examination and inquiry come to practically the same views quite independently of suggestions on my part. The coroner's court accepted the aspect of the case as presented by the medical witnesses and brought in a verdict in accordance therewith.

One question remains to be answered, Why on finding the pistol before him did he load it and put it to his own head? To find the reply the experienced psychologist will ask whether anything had come recently within the range of the mental experience of the deceased to suggest the act? There was this. Earlier in the week a report appeared in the papers of a clergyman shooting himself through the head in a similar manner. Though the deceased made no comment on it to his wife or to anyone it is improbable that it escaped his notice and, being in holy orders himself, he would not fail to be impressed by it. The record of an impression of this kind would complete the chain of inference. As it is we must be content with a surmise only, but a justifiable surmise. I would submit that a case of this kind is carefully to be distinguished from those sudden impulses which induce a man to throw himself from a high building or to jump into the water. In this form of self-destruction the restraining impulse from the "conscious" area of the cortex is overcome just as an incompetent driver is overcome by an ill-broken horse. In the present case there is no question of incompetence to restrain an impulse. The driver is absent, the horse is a runaway, and follows to the end a path down which its driver once led it for a short distance, merely intending to view the course taken by another to destruction.

Hampstead.

A RARE CASE OF INTESTINAL OBSTRUCTION RESULTING FROM A KICK IN THE RIGHT ILIAC REGION.

By GILBERT KEMPE, M.D. DURH.,
HONORARY SURGEON TO THE SALISBURY INFIRMARY;

AND

E. KEMPSON BROWN, M.R.C.S. ENG., L.R.C.P. LOND.

A STABLE-LAD, aged 17 years, was kicked in the abdomen by a horse on Oct. 8th, 1902. Three hours later Mr. Brown was called to see him. Mr. Brown gives the history of the case as follows.

I found him lying on his back with his knees drawn up, obviously in great pain and in a collapsed condition. Physical examination revealed superficial bruising in the right iliac region extending to the umbilicus. Both recti muscles were rigid and there was tenderness on palpation over the seat of the injury but no dulness to percussion. In the left iliac region there was a patch of dulness of the size of the hand. Respiration was quick and shallow and the temperature was 96·5° F. Inquiry into his previous history gave evidence of an attack of enteric fever two years previously. A catheter was passed and four ounces of normal urine were withdrawn. The patient was put to bed in a cottage, it being thought too risky to remove him immediately to a hospital. Hot fomentations were applied to his abdomen. Four hours later there were more pain and more abdominal distension. The patient was so restless that one-eighth of a grain of sulphate of morphia was given hypodermically. During the following night there was some vomiting, the vomitus being gastric. On Oct. 9th the patient's temperature was 101°, his pulse was 100, and respirations were 24 per minute. The abdomen did not move with respiration and was hyperæsthetic and markedly rigid. The vomiting had ceased but the bowels had not been opened. The patient was very restless all day and at night another dose of morphia was given. No more morphia was given, but for four days the bowels were not moved. On the 12th one-sixtieth of a grain of sulphate of strychnine was given hypodermically and the bowels acted freely and continued to do so for some days. On the seventh day (the 15th) the abdomen was only tender over the injured region, where there were some resistance on pressure and comparative dulness on percussion. The left-sided dulness had disappeared. Meteorism was present and at the end of the first week became very distressing, displacing the thoracic viscera, the heart's apex being in the third interspace internal to the nipple. Strychnine was again given with the result that the bowels were freely relieved, the meteorism was much lessened, and the apex beat came down into the fourth interspace. The patient was able to take and to retain nourishment. His general condition remained fairly satisfactory up to the sixteenth day after the accident. The temperature ranged from 99° to 101° and the meteorism was a troublesome symptom. After this the bowels became less and less active and the meteorism consequently increased. Strychnine failed to relieve these symptoms and purges produced only slight actions of the bowels. The temperature took a higher range (101° to 103°). The symptoms now became progressively worse, meteorism was intense, and the bowels became absolutely obstructed even to the passage of flatus. Vomiting set in. Immediate operation being considered imperative I called in my colleague Dr. Kempe of Salisbury. He concurred as to the necessity of operating and when the boy was anæsthetised a median incision below the umbilicus was made and the abdomen was opened. A hurried examination of the contents showed recent general plastic peritonitis, the coils of intestine being firmly bound together and to the parietes with white lymph, especially in the pelvis and right iliac region. There was no free fluid or any collection of pus. The lad's condition being extremely bad it was decided to relieve him temporarily by an enterotomy. Accordingly a distended piece of gut was opened and a Paul's tube was inserted. A large quantity of gas and liquid fæcal matter was discharged. After the operation the patient was manifestly better, the abdomen became flat instead of barrel-shaped, and the apex beat came down into the fourth interspace. The temperature never rose above 99° and there was free discharge of liquid fæces through the enterotomy wound, from which the tube was removed on the third day. For the first four days the patient was fed upon peptonised milk by the mouth and by peptonised nutrient enemata. The latter were not retained after the third day and were discontinued, soft solid food being then well borne. On the eleventh day after the operation the patient was removed to the Salisbury Infirmary under the care of Dr. Kempe with a view to further operation.

On Nov. 8th, the day after his admission to the Salisbury Infirmary, his condition was as follows. The patient was pale and very thin but felt comfortable and had no pain except from the excoriated skin around the fæcal fistula. Just below the umbilicus for about two inches was a granulating wound, in the centre of which was a fæcal fistula. The skin around was excoriated and raw. Nothing abnormal was felt in the abdomen which was flat, soft, and not tender. From the fistula came an almost constant discharge of liquid fæcal matter mixed with the undigested remnants of food and at times a flow of almost pure bile. In order to prepare him for a further operation to relieve the obstruction and to restore the continuity of the gut he was given a liberal diet by the mouth and at the same time nutrient enemata of peptonised milk and beef-tea were given every four hours. Many methods were tried to improve the skin around the fistula, but all methods of covering and protection had to be given up in favour of constant self-cleansing by the patient himself; he was provided with cotton-wool mops with which he wiped away all discharge at once, with the result that the skin rapidly improved. On Nov. 11th he had two evacuations per rectum, pale in colour and very offensive, which apparently consisted of the remains of the nutrient enemata and perhaps some fæcal matter which had been lying in the colon since before the first operation. On the 15th and 16th he seemed to have some obstruction above the fæcal fistula as this did not discharge; there was also some sickness and the upper abdomen became distended. Four grains of calomel overcame this and an enema was given per rectum but without result. On the 19th a similar attack occurred which lasted 36 hours but was relieved by an injection of plain sterilised water into the fæcal fistula. No other attack occurred and on Dec. 1st the lad was fatter and in better condition altogether. It was therefore decided to attempt to close the fistula and to relieve the obstruction, or, failing this, to anastomose the small intestine with the ascending colon. On the 4th the patient was anæsthetised and after the fæcal fistula had been closed by suturing its edges together the skin of the abdomen was thoroughly cleaned. An elliptical incision was then made around the fistula The incision was carried through the muscular and other layers into the peritoneal cavity. The portion of intestine and abdominal wall involved in the incision could now be lifted up. The distal portion of gut was followed down until it became involved in a dense mass of adhesions in the right iliac fossa. These were broken down with much difficulty and the small bowel was freed. An oblique scar-like ridge could be felt in the parietal peritoneum in the right iliac region. A portion of the sigmoid flexure was also involved in the adherent mass and this was freed and the bowel was traced from the fæcal fistula to the upper rectum. The bowel involved in the fæcal fistula presented the characteristics of the jejunum. The bowel above and below was clamped and excised and end-to-end union was effected by one of Stanmore Bishop's bobbins and two rows of fine silk sutures. The abdomen was cleaned and the abdominal wound was sutured with silkworm-gut. After the operation the patient became greatly collapsed and restless. A pint of normal saline solution was given per rectum and one-fiftieth of a grain of strychnine every two hours hypodermically. In the evening, as there had been no sickness, one grain of calomel every hour until four grains had been given was ordered, as it was thought advisable to excite peristalsis as soon as possible. Sips of soda-water and milk to the extent of half an ounce per hour were also allowed. On the next day (the 5th) he was fairly comfortable but looked very pale and pinched; his temperature was subnormal (98°) and his pulse (120) was very small and soft. There was slight abdominal pain. In the afternoon an enema of soap-and-water and turpentine was given, but with no result. Nutrient enemata were ordered every four hours. In the evening, about 7 o'clock, he vomited, bringing up a large quantity of curded milk (apparently all he had taken during the day); the milk was therefore stopped and sips of champagne, soda-water, and barley-water were substituted. At this time his temperature was still a little subnormal and the pulse was 120. The bowels had not acted and the nutrients were well retained. There was no abdominal distension. On the 6th his general condition was worse and he was lying low in the bed with drawn face and quite listless, the tongue was dry and brown, the pulse ranged from 130 to 140, and the temperature was 97°. Oral feeding was again tried and a small quantity of diluted milk resulted in the vomiting of about half a pint of bile-stained material. This kind of material was frequently vomited during the day. The abdomen was flat. There was no action of the bowels in spite of repeated enemata. Panopepton and champagne were tried by the mouth, but the second dose was vomited. He went gradually downhill until the 9th (five days after the operation). He had been repeatedly sick, the vomit being gastric and bilious. There had been no action of the bowels in spite of repeated evacuating enemata. On the 9th he appeared to be moribund. He was constantly vomiting brown bilious material, was listless and lying low in bed, and his surface and extremities were cold, shrunken, and bedewed with sweat. It was evident that effective peristalsis had not been set up and this was probably owing to the muscular coats not recovering from the inhibition brought about by the injury incurred by the visceral peritoneum during the separation of adhesions. The abdominal wound was therefore rapidly opened up, the presenting piece of small intestine was incised, and a Paul's tube was inserted No gas or fæces escaped. The intestine was flaccid and there were no signs of peritonitis. On the 10th there had been no discharge from the newly made fistula. He was vomiting constantly and looked likely to die at any time. In the evening the Paul's tube was removed and 15 ounces of warm water were injected into the proximal side of the fistula. Part of this returned and with it some very foul fæcal material. On the 11th the fistula was discharging well, vomiting was infrequent, and food by the mouth was being retained. By the 16th he was taking food freely, although there had been slight sickness from time to time. Between Dec. 16th and Feb. 16th, 1903, the patient continued to gain ground and put on flesh rapidly. He was fed liberally by the mouth and in addition was given nutrient enemata of increasing size until at the end of this time he was receiving from 18 to 20 ounces every eight hours, retaining and absorbing them, since very little waste came away with the morning wash out. Two small abscesses formed during this period, one behind the left ear and one over the left great trochanter. Both healed readily. On Feb. 16th he was brought up for his fourth operation, fat and well, and looking forward with keen interest to the prospect of recovery. An incision was made from the right side of the fistula outwards towards the lumbar region and carried down to the peritoneum. A finger was introduced and the loop of bowel forming the fæcal fistula was carefully separated and drawn outside the abdomen. The gut was clamped on either side about two inches away from the fistula. The loop of intestine between the clamps was then excised. The end of the distal portion was sutured, invaginated, and returned to the abdominal cavity. The end of the proximal portion was implanted into the ascending colon by the aid of a Murphy's button. Two rows of sutures were inserted round the button and a gauze drain in a split rubber tube was placed leading down to the anastomosis. The T-shaped wound was sutured with salmon-gut. The lad recovered well from the operation and had no bad symptoms. On the third day after the operation the bowels moved normally without any aperient and have moved daily since. The wound suppurated slightly, which was not to be wondered at considering the state of the abdomen, and the lad with a grin presented Dr. Kempe with the button on Feb. 23rd. The motions are slightly undigested but otherwise normal and the boy is rapidly gaining health and strength and also putting on flesh.

Remarks by Mr. BROWN.—From the standpoint of the physician I think this case is interesting from the following points. The marked dislocation of the apex beat, which was due obviously to the distension of the stomach and intestines, and which, although it was pushed up into the third interspace, was nevertheless half an inch internal to the nipple. The benefit obtained by the use of strychnine in the paralytic distension of the gut was most obvious and, on the other hand, the uselessness of intestinal disinfectants—i.e., salol, turpentine, &c.—to relieve the meteorism was also demonstrated. A comparatively low temperature with such an extensive inflammation was noteworthy and any large rise seemed to be clearly due to toxic absorption from the lumen of the intestine. The absence of suppuration was remarkable, since with the lowered vitality of the intestine it was only too likely that migration of organisms would take place.

Remarks by Dr. KEMPE.—This case seems to have been one in which a hæmorrhage into the abdominal cavity was succeeded by plastic peritonitis and intestinal obstruction. There was no evidence of any perforation of the hollow viscera and *the source of the bleeding would seem to have* been the parietal peritoneum in the right iliac region where a scar was found at the second operation. The value of enterotomy as a life-saving operation was amply demonstrated on two occasions. In each case the opening was made in the jejunum and yet the lad improved in condition and put on flesh with combined oral and rectal feeding. After the failure of the second operation the interest lies chiefly in the large amount of nutriment which was received and absorbed per rectum. As much as three pints of peptonised milk and beef-tea per diem were given in this way. For this I have to thank Sister Bartlett who was in charge and who carried out my instructions in the spirit as well as in the letter. Every care was taken not to overtax the forbearance of the rectum and lower colon and the final result was only obtained by careful training of these parts to do the work required of them. I would thank Dr. D. Ferrier, late house surgeon at the Salisbury Infirmary, *for his careful notes from which this* relation has been drawn. The successful results of combined oral and rectal feeding and the healthy character of the stools (which are almost completely digested) now lead me to believe that the lad's nutrition will improve, which [illegible]e in many recorded [illegible]l gut has been put out [illegible]

Note.—Since writing the above the patient has continuously improved and is now (August, 1903) *doing all* his ordinary work—viz., attending to his horses and riding at exercise every day. At first he gained weight too quickly, but now his weight is normal to him and he finds absolutely no inconvenience.

RESULTS OBTAINED AT MUNDESLEY SANATORIUM IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

BY F. W. BURTON-FANNING, M.D. CANTAB.,
PHYSICIAN TO THE NORFOLK AND NORWICH HOSPITAL;
AND
W. J. FANNING, M.R.C.S. ENG., L.R.C.P. LOND.,
RESIDENT MEDICAL OFFICER, KELLING SANATORIUM.

IT is now one year since we handed over the control of the Mundesley Sanatorium to Dr. Noel D. Bardswell and Dr. J. E. Chapman, so that the present seems a fitting time for the publication of the results which we obtained there. Though the Mundesley Sanatorium was not *opened till December*, 1899, we had patients under treatment in another house from the preceding June, so that the period which has elapsed since the first of the cases now recorded came under observation may be stated as four years. From June, 1899, to June, 1902, 143 patients were under treatment and we have been able to follow the after-history of 141, leaving two of whom we have been unable to obtain reports. In the absence of any universally recognised system of classification of cases and results we have adopted one which we find applicable for practical purposes. The patients are divided into two main classes according to the absence or presence of fever and each of these are subdivided thus: (1) febrile cases, (*a*) those with advanced disease and (*b*) those with slight disease; and (2) non-febrile cases, (*a*) those in which the disease is of long standing and in which the active stage is a thing of the past and (*b*) those of recent occurrence. The febrile cases were those presenting during their first week of sanatorium life an average afternoon temperature of more than 99° F. The temperatures were taken in the mouth. Great care was always exercised to get the true reading by giving the thermometer sufficient time—15 minutes—and by excluding the modifying influence of exercise and the application of cold, &c. The non-febrile cases were those where the average temperature for the first week of treatment did not exceed 99°. Cases of advanced disease we make to include those with distinct clinical evidence of a pulmonary cavity or with an affection of more than two lobes. Table I. shows the condition of our 143 patients on admission.

TABLE I.—*Showing the Condition of 143 Patients on Admission.*

Febrile Cases.

Advanced disease, 54 (or 37·76 per cent.).	Slight disease, 13 (or 9 09 per cent.).	Total, 67 (or 46·85 per cent.).

Non-febrile Cases.

Long-standing disease, 37 (or 25·87 per cent.).	Recent disease, 39 (or 27·27 per cent.).	Total, 76 (or 53·14 per cent.).

It will at once be observed that we were by no means able to confine ourselves to strictly selected cases. In the early days especially of sanatorium treatment in this country many patients applied for admission who had obviously passed the stage when material improvement in their condition was procurable. 91, or 63·63 per cent., had advanced or else long-standing disease. Of the non-febrile patients, in 37 the pulmonary tuberculosis had presumably come to a standstill but after more or less wrecking the lungs and not before the general constitution had become undermined. In many of these the secondary changes induced by old-standing consumption in the organs of digestion and of circulation as well as those in the lungs themselves, chiefly demanded treatment. A large proportion of these patients had previously undergone long courses of treatment at various health resorts and in other sanatoriums. The remaining 39, or 27·27 per cent., non-febrile patients were, of course, the most favourable of our cases for treatment. They had neither extensive lesions of the lungs nor marked constitutional symptoms. In some there had never been manifest fever, in others this had been subdued before they were sent to us.

In dealing with the results of treatment we record first the condition of the patient at the time of discharge and then follow his after-history up to date. The following headings are used in regard to results: (1) Arrest, with fitness for work again; (2) arrest, but under the obligation of leading such a carefully regulated life as precludes the safe resumption of serious work; (3) improvement, where the general conditions are ameliorated, but where the occasional or constant persistence of fever indicates some activity of the disease; (4) no improvement, where fever and other symptoms remained unchanged; and (5) retrogression, including patients who died in the sanatorium.

TABLE II.—*Showing the Results of Treatment.*

Arrest with fitness for work.	Arrest with inability to work.	Improvement.	No improvement.	Retrogression.
47 (or 32·86 per cent.)	36 (or 25·17 per cent.)	38 (or 26·57 per cent.)	8 (or 5·59 per cent.)	14 (or 9·79 per cent.)

From Table II. it will be seen that in 84·60 per cent. arrest of disease or distinct improvement was attained, while in 15·38 per cent. no benefit was obtained. We now proceed to consider the progress made by our patients subsequently to their discharge from the sanatorium and up to the present date—that is, for the period of four years that have elapsed since our first patients left the sanatorium and of one year since the discharge of the last of the patients (see Table III.).

TABLE III.—*Showing the Progress of the Cases subsequently to Sanatorium Treatment.*

—	On discharge.	Satisfactory condition maintained.	Relapse but living.	Dead.	Total living.
Arrest with ability to work.	47 (or 32 86 per cent.)	42 (or 89·36 per cent.)	4 (or 8·51 per cent.)	1 (or 2·13 per cent.)	46 (or 97·87 per cent)
Arrest with inability to work.	36 (or 25·17 per cent.)	22 (or 61·11 per cent.)	10 (or 27·77 per cent.)	3 (or 8·3 per cent.)	32 (or 88 88 per cent)
Improvement.	38 (or 26·57 per cent.)	8 (or 21·05 per cent.)	12 (or 31·58 per cent.)	18 (or 47·3 per cent)	20 (or 52 65 per cent.)
No improvement.	8 (or 5·59 per cent.)	0	0	7 (or 87·5 per cent.)	0
Retrogression.	14 (or 9·79 per cent.)	0	0	14 (or 100 per cent.)	0

An examination of this table shows that arrest was secured in 58·03 per cent. of all the patients and that as many as 93·97 per cent. of these are still living. Further, that improvement which did not, however, amount to arrest was obtained by 26·57 per cent. and that 52·65 per cent. of these patients are still living. If we now pick out the most favourable classes, those with early disease unaccompanied by fever or whose disease was slight and febrile, we find that in no single instance did improvement fail to be obtained. In 76·92 per cent. in each group such satisfactory arrest of disease occurred as to allow of the patient resuming his work, while in 30·76 per cent. of the former and in 15·38 per cent. of the latter group arrest occurred, but the patient's well-being depended on his following more or less an invalid's life. In the four years and less that have passed since the discharge of these patients from the sanatorium only four, or 7·69 per cent., of the whole number have died, while 40, or 76·92 per cent., have maintained their health and ability to follow an employment.

TABLE IV.—*Showing Particulars of Patients Admitted, Living, Fit for Work, and Dead, Grouped in Febrile and Non-febrile Cases.*

Febrile Cases.

Admitted.	Living.	Fit for work.	Dead.
Advanced disease, 54.	21 (or 38·88 per cent.)	0	32 (or 59 25) per cent.)
Slight disease, 13.	11 (or 84·62 per cent.)	10 (or 76·92 per cent.)	2 (or 15·33 per cent.)
Non-febrile Cases.			
Long-standing disease, 37	30 (or 81·08 per cent.)	0	7 (or 18 92 per cent.)
Recent disease, 39	36 (or 92·30 per cent.)	30 (or 76·92 per cent.)	2 (or 5 13 per cent.)

Of the 43 patients who have died (see Table IV.) four died in the sanatorium. In the cases of two others death did not result from tuberculosis directly.

A point which is of special interest to us is the healing of the disease as evidenced by the complete disappearance of physical signs. In 17 (or 11·88 per cent.) of our 143 cases the signs have entirely cleared up. In another two cases the diagnosis had to be made on other evidence, no physical signs having existed at any time. The clearing up of physical signs is chiefly a matter of time. It is excessively rare to find in four months—the average time spent by our patients in the sanatorium—any very marked change in the stethoscopic examination of the chest, notwithstanding the remarkable change that may have come over the individual's general being, but if many more months are allowed to elapse and the patient's physical examination is from time to time carefully conducted and compared with former records an unmistakeable improvement is often noted. Without doubt râles at one time audible over a third of a lobe may vanish, breath sounds which were cavernous over a very small area may become merely weak, and dulness extending over a whole lower lobe, with perhaps bronchial breathing and râles indicating a tuberculous affection of the pleura and the surface of the lung, may clear up if only watched for a sufficient number of months or even years.

One more piece of information we wish to extract from our cases, and that is in reference to change of climate. A good number of our patients, 32 in all, on leaving the sanatorium went to various health resorts on the Continent and elsewhere abroad, which are more or less renowned for the treatment of consumption. In many cases the principles of health maintenance had been thoroughly learnt and the patients chose to finish their cure in a sunnier and brighter climate; in others, progress with us had not been satisfactory, and it was determined that sanatorium treatment in England having more or less failed the effect of some recognised health resort be tried. Now the subsequent progress of these patients has been closely watched with particular curiosity and interest and we can honestly state that in no single instance has the course of the disease been materially different after going away than it would presumably have been had the patient remained in his own country. There is one class of consumptive, we admit, for whom a better winter climate than England, anyhow that of its east coast, can be found, and this class we never retained at Mundesley: we refer to the subjects of old-standing pulmonary tuberculosis with defective circulations and inability to stand cold, with cartarrhal symptoms and, perhaps, affection of the kidneys or other internal organs.

In our few cases of pulmonary tuberculosis associated with emphysema and asthma the patients did better than we anticipated. We feel some hesitation in referring to the disappearance of tubercle bacilli from the sputum, for it is hard to say when they have vanished for good. Repeated examinations of the sputum of a patient progressing very favourably may fail to discover bacilli, but on another occasion the same patient may suffer from some accidental catarrh and tubercle bacilli may reappear in the expectoration. In the cases of our best results all sputum ceased; *in some of these bacilli persisted so long as there was any* phlegm to examine and in others a gradual diminution in their number had been noted.

In conclusion, our experience emphasises the extreme importance of the early recognition of pulmonary tuberculosis. If adequate measures are taken in the very earliest stages of the malady *we may hope to restore some* 75 *per cent. of our* [illegible] over the bacillus depends, we believe, on the patient constantly living by rules which are based on careful observation of the [illegible]s. He must expend in [illegible] safely be spared by the [illegible] check and *he must take* no liberties with health. The supreme importance of these and other principles of sanatorium treatment is apt to be lost sight of by those relying on mere change of climate for the treatment of consumption.

ON THE TREATMENT OF THE SUMMER DIARRHŒA AND VOMITING IN INFANTS.

By H. T. HICKS, F.R.C.S. Eng.,
OBSTETRICAL REGISTRAR AT GUY'S HOSPITAL; LATE RESIDENT MEDICAL OFFICER AT THE EVELINA HOSPITAL FOR SICK CHILDREN.

THE question of the treatment and nursing of infants' summer diarrhœa and vomiting is becoming urgent again. It must be understood that this short account deals with it simply from the practical point of view, giving the experience of those methods which to my mind have proved most successful while [illegible] It has been said that [illegible] plaint die from thirst [illegible] the circulation and the circulation from the tissues. The fluid supply is cut off by the damaged alimentary canal refusing to tolerate the input. All treatment then is directed against the cause—e.g., to clear out by the least irritating means the toxins which are the primary cause and at the same time to introduce a fluid that can be retained and absorbed. One has only to see the baby, lying in his cot, listless, restless, collapsed, with eyes half closed, and then to notice him rouse up suddenly with an eager look when a little water is placed upon his lips, or even if only a spoon clicks against the feeding glass. The infants must have fluid, they ask for it, and their appeal is physiological, *even though the cause of their want be pathological.* The treatment of this fatal disease consists almost entirely in good careful nursing, and this nursing resolves itself into three parts—feeding, rest, and cleanliness. Drugs have shown themselves to be of very doubtful assistance with one exception, oleum ricini, and this seemed most effectual given in one initial aperient dose, followed after a day by a course of from six to eight six-hourly drachm doses of the mistura olei ricini, B.P., with the addition of sodium bicarbonate, two grains to each dose.

Ordinary, not excessively bad, cases generally respond to the following course. On admission a nice warm bath is given and then, with the child's head hanging over the side of the cot, the stomach is washed out with slightly alkaline water, and when this comes away clear there are passed down the tube one drachm of oleum ricini and an ounce or two of albumin mixture with a drachm of beef-juice or raw meat-juice. If the child keeps this down he is fed again by the mouth with the same quantity in two hours. If, however, the food is rejected smaller quantities are given at shorter intervals, even as frequently as a drachm every quarter of an hour. If the baby continues to be sick the beef-juice or raw meat-juice is omitted and if vomiting still persists all feeding by the mouth must be stopped and intracellular infusion of normal saline solution is resorted to.

This brings us to the worst class of cases of diarrhœa and vomiting, which are admitted listless, with sunken eyes, retching, and looking almost past help. These, after an initial warm bath, are infused with normal saline solution, about four ounces every six hours with—if absolutely necessary—the addition of a very little brandy. I lay stress on the fact that an infusion of a small amount is more beneficial than one of half a pint or more, this latter being frequently followed by considerable hyperpyrexia, *albuminuria, and in some cases general œdema.* It is important to infuse extremely slowly. Repeatedly, when I infused rather rapidly, the temperature rose quickly. The normal saline solution enters the loose, baggy folds so readily and with so little resistance that one may be tempted to inject too fast. An ordinary four-ounce brass *syringe with a piece of rubber tubing* and a hypodermic needle, all previously boiled, seem to answer very well as an infusion apparatus for babies. Washing out the stomach [illegible] retained washes out the lower part of the bowel. Feeding entirely by the intracellular way can be continued for about 24 hours if necessary and then drachm doses of albumin *mixture tried* and, if retained, increased, and small quantities of beef-juice or raw meat-juice added. The infusions should be lessened and stopped altogether when the patient is able to take a sufficient quantity by the mouth. After 24 hours of feeding with albumin mixture we can attempt a gradual return to milk and we begin by adding drachm doses of peptonised milk or Benger's food to the albumin mixture, increasing gradually, until we give either *peptonised milk* or Benger's food undiluted. Benger's food is more popular with babies than peptonised milk. Before returning the baby to his mother we must, however, get him back to ordinary milk diet and it is found that a food which is borne better than the old milk and lime-water or barley-water mixtures is one of milk and an oatmeal gruel. A specially prepared oatmeal (Knorr's Hafermehl) seems to agree excellently with these babies. To this course of treatment we have returned again and again after various excursions from time to time to different *other forms of feeding*; we have used all kinds of cream mixtures; we have used whey, but none of these were satisfactory.

There are a few more points worth mentioning: we give very little brandy, and if it has to be ordered it is administered by preference hypodermically so as not to irritate the stomach. We bathe the babies at least twice a day, but very, very gently, moving them as little as possible. The bath often seems to allay the thirst to some extent and always the restlessness. Except for the bath we keep the baby in absolute seclusion. We choose the quietest corner of the ward and we only disturb him when absolutely necessary. The nurse attends to him before feeding and immediately the feeding is completed the curtain is drawn over the child—we keep all bad diarrhœa and vomiting cases in curtained beds—and the baby is left "in retreat" until the next feed, if possible. The mouth of these patients requires a great deal of attention, and nothing keeps it better than ordinary cold water, or slightly alkaline water (sodium bicarbonate one grain to the ounce). It must always be washed out before food and—if we can risk it without exciting fresh vomiting—also afterwards. Medicated mouth washes are generally harmful through having too decided a taste, so causing a recurrence of sickness. The period when the care of the mouth is most important is while intracellular feeding only is being carried on. The swabbing of the mouth then does not only serve the purpose of keeping the part clean but also of allaying the thirst and the accompanying restlessness. We must not, however, allow ourselves to give in to the baby's evident craving for fluid which he shows by eagerly sucking the wet rag we are using and let him have a drink of water, because this misplaced pity has again and again re-started the barely arrested vomiting. Another point which the nurse must be extremely careful about is the thorough scrubbing and disinfecting of her own hands after having attended to the infant. This is most essential, as by infecting the baby's food with even the smallest particle of fæcal matter the sickness, which has just been stopped with great difficulty, may be started again. So much importance is attached to this matter in some children's hospitals on the continent that special nurses are told off to do the feeding, while others attend to the cleaning of the patients.

The above *régime* applies exclusively to acute cases. For chronic cases of diarrhœa and vomiting who cannot retain milk and milk mixtures, we have found malt soup very satisfactory. Babies can be kept on this food for as long as three weeks and then gradually be trained to take ordinary milk, generally *viâ* Benger's food. Horlick's malted milk also has acted fairly well in some cases of this kind. A new preparation, "pegnin," which has the great advantage of reducing the casein in cow's milk to a very fine, flocculent curd, promises to become a valuable addition to the infant's dietary. Another experience which we have had in obstinate cases of habitual vomiting is that some will not reject their food if it is introduced by the nasal tube, whereas all attempts at feeding by the mouth are useless. If to the treatment of chronic cases we could add sunshine and good, fresh, bracing country air, we might hope to carry it out with very much more chance of success. I append the formulæ of the foods above mentioned hoping they may prove useful.

Albumin mixture.—Beat up the white of two fresh eggs and add gradually one pint of cold, sterile normal saline solution. Stir up well and strain through muslin. Keep cold.

Beef-juice (Guy's Hospital Pharmacopœia).—One pound of lean beef is finely chopped and added to one pint of water. This mixture is then gently heated (being constantly stirred) until the temperature is 55° C. (130° F.) at which it is kept for 15 minutes. To this are added three ounces of beef-tea and a small teaspoonful of salt. The whole is then strained through muslin over a hair sieve and filtered into a flask in which it is to be kept. If placed in an ice-box the juice will keep for two or three days.

Raw meat-juice.—One pound of lean beef is finely chopped. Add to it five ounces of water, mix up well, and stand on ice for three hours. Then strain through muslin, the meat being well squeezed. Keep in the ice-box.

Malt soup.—50 grammes (13 drachms) of wheat flour are well mixed up with one-third litre (12 ounces) of fresh cow's milk and the mixture is passed through a hair sieve. In another vessel 100 grammes (three ounces two drachms) of extract of malt are dissolved in two-thirds of a litre (24 ounces) of water at 50° C. (122° F.) and to this are added ten cubic centimetres (two and a half drachms) of an 11 per cent. solution of potassium carbonate. The two preparations are then mixed and boiled up quickly.

Knorr's Hafermehl.—Supplied by Messrs. Allman, 9, Cullum-street, Fenchurch-street.

Pegnin.—Supplied by Farbwerke, 51, St. Mary-axe, E.C.

THE

SUCCESSFUL TREATMENT OF SPORADIC DYSENTERY BY APLOPAPPUS BAYLAHUEN.

BY WILLIAM FINGLAND, L.R.C.P. & S. EDIN.

IT falls to the lot of most practitioners to have from time to time to treat cases of sporadic dysentery, colitis, or one of its protean forms, and when a more or less chronic character is assumed no disease is so rebellious to treatment. And when we consider the grave pathological condition of the colon this is not a matter of much surprise. Briefly, the mucous membrane is thickened, œdematous, congested, and cyanotic; the eminences and depressions on its surface are practically obliterated. It is bathed in a muco-serous exudation and its surface is covered with hæmorrhagic petechiæ and suppurating foci. For the amelioration and cure of these conditions many remedies have been suggested, which I will mention later, but from collected experience the disease tends to pursue a chronic and incurable course.

The drug which I wish to introduce to the notice of the profession is indigenous to South America and in Chili and other provinces of the west coast of South America it is considered a specific for this disease. It is called locally hysteronica and its botanical name is Aplopappus Baylahuen. Messrs. Parke, Davis, and Co. of London have prepared and supplied me with a fluid extract thereof. The plant belongs to the class of balsams. The fluid extract is a dark green gummy fluid, of a syrupy consistence, and has a peculiar odour. It is not miscible with water and requires to be prescribed alone and not in combination. The dose is 20 minims thrice daily, suspended in a tablespoonful of cream, milk, or freshly prepared almond emulsion. During the exhibition of this drug the diet must be carefully supervised, all vegetables and fruits prohibited, and a diet of beef, mutton, fish, and light farinaceous dishes enjoined, with hot water and milk to drink, the latter with some caution. In the three cases (each possessing in a marked degree the typical symptoms of this disease) which have come under my notice and presently to be described the curative effects of this drug were so conspicuous that I hope other members of the profession, with more frequent opportunities, will give this drug a more extended trial, as judging from my own success it would appear to be a specific for this troublesome malady.

CASE 1.—The patient was a lady who was believed to have contracted the disease from drinking water when staying at Heswall, Cheshire (before the present water-supply was introduced). She has had many attacks during the last ten years, each attack increasing in severity. The symptoms were quite usual—nausea, vomiting, thirst, pain, tenesmus, tormina, with incessant diarrhœa accompanied with scanty muco-purulent dejecta and copious hæmorrhages. The last attack occurred two and a half years ago, when all the usual remedies were prescribed, including ipecacuanha, magnesium sulphate, and the newer astringents such as tannoform, tannigen, and fortoin. The colon was also irrigated with silver nitrate (which had formerly afforded good results), starch and opium, supra-renal extract in thin gruel, and other soothing astringents and sedatives with very little benefit. Hysteronica was prescribed for the first time, when all the symptoms gradually disappeared and the patient has now been free from any recurrence for two and a half years.

CASE 2.—A nurse in a Liverpool hospital contracted the disease when on a visit to Scarborough. She suffered from similar symptoms to the preceding, with very brief intermissions for four years. Latterly the anæmia and asthenia were pronounced, she was practically bedridden, and contemplated giving up her occupation. She had been under the care of several members of the staff of that institution but did not show any progress towards recovery. I mentioned this drug to her then medical attendant and induced him to prescribe it. After taking a few doses the improvement was marked and continuous, her usual health and vigour being rapidly restored. About 18 months have now elapsed without any return of the symptoms.

CASE 3.—An engineer aboard a steamship trading between Liverpool and the West Indies stated that he had contracted the disease from using impure drinking water, in those islands. His symptoms were similar to the above but not so severe as entirely to prevent him from following his work. I had tried magnesium sulphate but with no benefit, when I prescribed hysteronica which rapidly removed all symptoms of the disease. I last saw this patient on June 29th, 1902, when he was quite free from any recurrence and I have since been informed that he has remained in perfect health.

Liverpool.

A CASE OF TRAUMATIC TETANUS TREATED WITH ANTITOXIN; DEATH.

By H. S. ELWORTHY, L.R.C.S. Eng.,

CASUALTY OFFICER TO THE GREAT NORTHERN CENTRAL HOSPITAL.

TETANUS, fortunately not a common disease in this country, is one of those which still maintain a very high mortality and therefore any therapeutic measures that may be taken to cure it must be of great interest to the medical profession, whether successful or otherwise. In the days before antitoxin the mortality from traumatic tetanus was something like 80 or 90 per cent., and at the present time, so far as I can gather, it amounts to about 50 per cent. or more, as unfavourable cases are probably not so often recorded as successful ones.

The case I have to relate was that of a boy, aged 14 years. He had had more than the usual share of illnesses and accidents and was not robust. He "picked at his food" and was difficult to feed at all times, was slight of build, and what one would describe as a little delicate. While playing in a cricket field on June 27th he stepped on a spike of some kind which perforated the sole of the left foot. Medical aid was not sought for. The wound suppurated and apparently got well, so that no more was thought about it. On July 2nd he fell down on his back but made no complaint of it. On the 4th he began to complain of pains in the back, but thinking it was only a little rheumatic stiffness he went away and spent the day with a relative. On the morning of the 5th, however, he found that he could not open the mouth properly and had spasms of the muscles that caused him to bend forwards and several times he fell down on his hands and knees.

When I saw him for the first time he was walking about the room and a spasm occurred about every five minutes, causing the head and back to bend forwards. The pain was not severe and passed off in a few seconds. He declined to lie down as that caused more pain. He bit his tongue slightly in one of the spasms. The mouth opened about half an inch. There was no tenderness and the pains were about the trapezii muscles, none about the jaws. On examining the foot a small piece of grit, like cinder, and of about the size of a millet seed, was found imbedded in the skin lying in a smooth cavity. This was removed and the wound was dressed with a 1 in 20 solution of carbolic acid. The parents had given him a dose of liquorice powder without result. Three grains of calomel were given at once and a mixture of bromide and chloral was ordered to be taken every three hours. At 3 P.M. the spasms were still recurring about every five minutes. He had tried to sleep but was awakened in about ten minutes by a spasm, or else just before becoming unconscious he got clonic contractions of the hands and arms. He was becoming tired. The abdominal muscles were rigid, as were also those of the back. The spasms caused the expulsion of large quantities of flatus. By 6 P.M. I had procured through a druggist some tetanus antitoxin from the Jenner (now Lister) Institute of Preventive Medicine. As it was on Sunday the special messenger found some difficulty in getting it, having to try at several places before he could obtain any, and this caused some delay. Mr. E. H. Hare, who saw the patient in consultation and rendered valuable assistance on several occasions during the illness, administered chloroform while I excised the wound from the sole, swabbed the base with chloride of zinc, 40 grains to the ounce, and injected ten cubic centimetres of the antitoxin under the skin of the abdomen. He slept for about one hour after this and then the spasms returned as before. I could see no improvement, although the patient said that the pains were less severe but more frequent. His face was red, the skin was sweating, the pulse was irregular (just after a spasm) but of fair volume, and the temperature was 98.8° F. At midnight the spasms were becoming more frequent, so another injection of ten cubic centimetres of antitoxin was made under the skin. He slept better—as much as 20 minutes at a time between the spasms—and felt better. Urine was passed into the bed on several occasions, so there was no occasion to use a catheter.

On the 6th at 10.30 A.M. a third injection was made into the left thigh and the foot was dressed as the bandage had become loose. At 12.40 P.M. he seemed quieter but attempts to feed him by the mouth brought on the spasms. The head was now retracted and the spasms caused arching backwards but were never severe nor was there any risus sardonicus at any time. At 5 P.M. he had been asleep for an hour after taking the medicine. He was then taking 15 grains of bromide, 15 grains of chloral, and five minims of tincture of cannabis indica every three hours, but the spasms now returned just as frequently, sometimes at intervals of five or six seconds. He was again put under chloroform and ten cubic centimetres of antitoxin from another source were injected into the spinal canal between the third and fourth lumbar vertebræ and the foot of the bed was raised nine inches so that it should gravitate towards the medulla. Half an hour afterwards he had a succession of spasms coming on every few seconds. He then slept for an hour, having occasional spasms at intervals of from 20 to 40 minutes. He could now turn on his side, which he could not do before owing to rigidity of the arms. He paid no attention to sounds, so that a smoking concert across the road had no effect on him nor the accidental slamming of the door by the wind. Ten grains of calomel were administered as the bowels had not acted.

On the 7th, at 9 A.M., the patient had had a fairly good night. The bowels had not been opened. The spasms came on severely from 8 to 8.30 A.M., they were more sudden and jerky and caused a sort of cry from the contraction of the abdominal muscles expelling air from the lungs. There were clonic spasms as well. Food could not be taken by the mouth. He was again chloroformed and a second injection was made into the spinal canal at 9.45 A.M. A stomach tube was passed and an egg with five ounces of milk and some meat extract were given and a nutrient suppository was inserted into the rectum. The foot of the bed was raised as before. Some antitoxin was also applied locally to the foot. The spasms began again at 11 A.M. and became rapid and more severe at 11.15 A.M., there was a succession of about 16 in a short interval. He was sweating, the pulse was 96 and fairly regular, the respiration was 46 and rather shallow, and the temperature was 101.2°. At 12.50 P.M. medicine was passed through a funnel and tube into the mouth. He could swallow with difficulty. On one occasion the right eye was found deviating outwards. At 1.25 P.M. no improvement was noticed and a sixth injection of antitoxin was given under the skin. From the morning until the end chloroform was given at each spasm, sufficient to relax the muscles. They were occurring from every 10 to 15 minutes. In the afternoon the features looked drawn and pinched. The patient was fed through the tube every five hours with milk, egg, and extract of meat, and when he could not swallow the medicine it was given him with the food. At 5.30 P.M. he began to have the appearance of septic fever. As the bowels had not acted since the commencement of the illness a turpentine enema was given and was returned only a little stained by fæces. At 7.30 P.M. he collapsed and appeared to be moribund, the pulse was intermittent, irregular, and feeble, and the breathing was jerky and shallow. The eyes were semi-closed and the lips and the tongue were dry. The patient however, rallied and at 8.30 P.M. was given a nutrient enema which was expelled about ten minutes afterwards, just as the suppositories were. He also involuntarily expelled his evacuations with some force after this. The spasms occurred now at intervals of from five to eight minutes. The temperature was 104° and he was sponged at intervals, which brought it down to 102.8° by 11.20 P.M. The skin over the bony parts was red and threatening bed sores. It was rubbed with spirit each time he was turned over.

On the 8th he was fed again at 1.40 A.M. and some opium, digitalis, and strophanthus were added to the chloral mixture. On passing the stomach tube it was firmly gripped by muscular contraction. The spasms continued with some regularity every seven or eight minutes but were less severe. There was a slight expiratory cry, with arching of the back and retraction of the head, with general rigidity, for a few seconds, then a succession of very rapid and shallow breaths as if the diaphragm could work to a slight extent but was hampered by the abdominal and thoracic muscular rigidity. This enabled a little chloroform to be absorbed and the breathing became normal and the muscles relaxed in a few seconds. At about 5 A.M. the patient was unconscious and the corneal reflex was absent. He was rather blue about the lips and the face had a dirty septic-looking colour. The temperature was 107°, the respiration was 54, and the pulse was from 120 to 140 but difficult to count. He was sponged again and the foot was dressed with carbolic acid and gauze. He was fed at 6.50 A.M. He had a longer interval from spasms—about three-quarters of an hour. At 7.30 A.M. the temperature was 105°. He had eight more spasms between this time and 10.33 A.M., when he died in one of them, the temperature just before death being 105°.

Dr. F. W. Andrewes very kindly examined the piece of skin removed from the foot and reported that he had found one or two long slender bacilli in the tissue—staining by Gram's method—which were not sporing and hence could not certainly be identified as tetanus; that there was inflammatory infiltration consisting chiefly of polynuclear leucocytes beneath the site of the wound; that horizontally I had cut far wide of it, but vertically it extended to the confines of the piece removed and probably deeper still. At the time I could not see with the naked eye that I had not got beyond the inflammatory area, nor feel any difference with the finger.

The convulsions throughout were mild in character—nothing more than one gets in ordinary epilepsy—and death appeared to have resulted from the high temperature and exhaustion from the number of spasms.

The antitoxin in this case appeared to have little or no more effect than the chloral and bromide and the injection into the spinal canal to be no more efficacious than under the skin. The question of injecting into the ventricle of the brain had been discussed but it was decided not to do so as there did not appear sufficient evidence that the results obtained justified the additional risks from the operation. Physostigmine has been used in some cases with success—so, indeed, have many other drugs—and more often without. It is a distinctly depressing remedy and for that reason I did not feel inclined to use it. The serum treatment is not as generally successful as we could wish and it is to be hoped that further researches on toxins, immunity, &c., may result in the production of a serum that will be satisfactory in all cases. It is quite possible that it may have had some effect in mitigating the severity of the spasms. The local application at the commencement might be of some use as an addition to the injections.

Ehrlich's theory is a distinct advance in giving us a vague idea of the complicated chemical changes that occur in the body and makes one speculate on the effect of injecting serum. If it were simply a question of neutralising a poison there would be nothing to worry about, but when we think of the intricate chemical grouping of such complex bodies as have been called amboceptors, haptophores, the various antibodies, toxoids, &c., one is inclined to marvel as to whether the injection of an antitoxin may not in some way interfere with the natural production of antitoxin by the cells of the body, that is to say, interfere with the natural cure rather than promote it. The same reasoning, however, probably applies to the action of drugs as well, of which the medical man has been said to know little. Perhaps we shall know more by the end of the century.

Crouch-end, N.

THE TREATMENT OF CONGENITAL PHIMOSIS.

BY J. F. WOODYATT, M.R.C.S. ENG., L.R.C.P. LOND.,

PRINCIPAL MEDICAL OFFICER, HALIFAX UNION POOR-LAW HOSPITAL.

I HAVE lately performed a new operation for phimosis which is very simple and which gives better results than circumcision, inasmuch as after the operation the glans is left covered by a foreskin which is easily retracted and replaced. Before I describe the operation I should like to emphasise the fact that in congenital phimosis the constriction which prevents retraction of the prepuce is caused by a tight ring of mucous membrane just inside the prepuce. The skin of the prepuce is, in my opinion, never redundant; it is very elastic and is never the cause of the condition. If more proof is required that phimosis is caused by a stricture of the mucous membrane let us examine a case of paraphimosis which has been reduced by cutting the tight band at the back of the glans. It will be found that the incision is quite out of sight inside the orifice of the prepuce. Now the cause of the condition should guide us in the treatment of these cases and my operation consists of cutting the constriction and preventing its recurrence by the introduction of sutures. I have performed the operation in a number of cases and the result has always been perfect—that is, a glans covered by prepuce which is easily retracted and replaced. Why the operation of circumcision has been so frequently performed I fail to see. The object of the surgeon should be to leave the deformed organ in a normal condition and not to mutilate it by cutting away the covering of the glans. Let us apply our conservative surgery to the penis and circumcision will no longer occupy a place in modern surgery.

My method of operation is to hold the penis between the left thumb and forefinger, to retract the prepuce as far as it will go, and then with a pair of sharp-pointed scissors held in the right hand to cut the stricture first on the right side and then on the left side. It is not necessary to slit up the mucous membrane far back but it should be done equally on both sides. When the stricture is relieved I retract the prepuce and separate the mucous membrane from the glans and also remove any smegma there may be around the corona. Now by introducing one suture into each cut the operation is complete. Each suture is introduced so as to make what was a longitudinal incision into a transverse one. This is done by joining the commencement of the incision to its termination in the same way that simple stricture of the pylorus is now relieved. I use fine chromic gut and an ordinary sewing needle. No after-treatment is necessary. The little wounds are inside and will heal readily if left alone. If the sutures do not come away of themselves they may be removed in a week or ten days, when it will be found that the prepuce is easily retracted and replaced.

Halifax.

Reviews and Notices of Books.

Life and Labour of the People of London. By CHARLES BOOTH, JESSE ARGYLE, ERNEST AVES, GEORGE E. ARKELL, ARTHUR BAXTER, and GEORGE H. DUCKWORTH. Final volume. Notes on Social Influences and Conclusion. London: Macmillan and Co., Limited. New York: The Macmillan Co. 1902. Pp. 451. Price 5s. net.

THIS is the seventeenth and last volume of Mr. Charles Booth's great work. Roughly speaking, the latter half of it is devoted to giving an abstract of the contents of the complete work (pp. 225-439). The first series (of four volumes) is devoted to Poverty, the second (of five volumes) to Industry, and the third (of seven volumes) to Religious Influences. The final volume is entitled "Notes on Social Influences and Conclusion." "My work now completed has been from first to last," the author says, "dedicated to my wife without whose constant sympathy, help, and criticism it could never have been begun, continued, or ended at all." And a noble work it is in its aim and in its execution. The reader who looks for teaching finds facts from which he has to construct his own inferences. "Some introduced views," says Mr. Booth, "and convictions have been intentionally allowed to show themselves here and there in comments made, but no body of doctrine is submitted."

The idea with which Mr. Booth began his work was that every fact which he needed was known to some one—the information had only to be collected and put together. But it was necessary to see that the statements received were really facts; they had, as he puts it, "to be reduced to some common measure of validity." Those obviously false had to be rejected, the improbable withheld, the exaggerated toned down, and the requisite emphasis given to an understated truth. A large inquiry made on these principles naturally demanded much careful work on the part of painstaking men of acute observation and high intelligence. Mr. Booth had for the most part the same co-workers throughout; their individual views were various but they worked to the common end of unbiased exposition and their anticipations as to the outcome ("perhaps the most subtle form of bias," as he keenly remarks) differed greatly and changed from time to time as the facts accumulated. Mr. Booth was fortunate in his assistants; the fact that he selected them so wisely shows his judgment. There is constant evidence that the inquiry was carried out by men of clear vision who were also men of the world. There is no blinking of plain facts. The working of things is plainly stated. The brothel and the various forms of prostitution are, for example, described in the plainest language, so that the thoughtful among us may realise the nature and surroundings of the social evil which we wish to cure. It is, perhaps, not too much to hope that a larger knowledge of its nature and manifestations may lead to measures more likely to be useful than any at present attempted.

It might be imagined that a book with such a scope, being full of statistical details, would be dull. In such an inquiry statistics are of course necessary, but they do not appeal to everyone. Mr. Booth appears to take a positive pleasure in them, but he has no word of censure for the weaker brethren who do not share it. "If I may borrow from the vocabulary of a more charming art, I would," he says, "in the opening phrases of my finale introduce again the statistical motif of earlier volumes," and he goes on to advise those whose souls are not attuned to figures and who find no harmony in their tabular arrangement to pass lightly over these pages of his score. This advice may be followed by those to whom it is addressed. They will find that more remains behind—that the residue is intensely interesting and often lightened by humour. There is, for example, an instructive story of a good clergyman who gave pecuniary assistance to one of his flock who was unable to work because he lacked the necessary tools of his craft. The charity was first bestowed—inquiry followed. The recipient was a well-known burglar. To many people it will doubtless come as a surprise that the occupations of the people are perfectly well known to those who work amongst the poor and that no secret is made of the fact by those who follow some one of the less esteemed industries. A deaconess was hailed from a window by a man who asked her to come and dress a wound on his hand. In answer to her inquiry as to how the accident happened he told her that in getting out of a gentleman's window the night before he had fallen on the railings.

The points dealt with in this volume are arranged under four chief headings: (1) Some Comparisons; (2) Habits of the People; (3) Notes on Administration; and (4) Conclusion. Overcrowding and extreme poverty do not always go together —a point which cannot have failed to strike anyone even moderately familiar with the life of the town. The very poor are always overcrowded but they are not the only ones affected. Those who have to live near their work have often to pay huge rents for scanty accommodation. The localities where this state of things exists are given in detail. Mr. Booth refers with due praise to Mr. Rowntree's inquiry into the poverty of York—a city in which fewer recent sanitary improvements have been made than is the case in London.

The subjects considered in Part II. are: (1) Marriage and Morality; (2) Sundays, Holidays, and Amusements; (3) Betting; (4) Drink; (5) Clubs; (6) Notes on Pawnbrokers and Money-lending; and (7) Economic Conditions of Life. The few who know intimately the life of the people of London will be struck with the accuracy of the picture here presented, and those now ignorant, who wish to know it, will be able to understand something of its true inwardness, for the book presents facts without impressionism or reserve. The ethical standard concerning marriage and morality differs greatly in the case of the poorest and the richest classes, but public opinion is not less strong amongst the former. The evil effects of Bank holidays and the increasing curse of betting are laid bare and the question of drink is considered calmly and without bias. The use and abuse of clubs are very clearly indicated. There is little moralising in the book but a comparison on the modes of thought of the Eastern and the Western nations must be cited:—"The Eastern method is to transfer the struggle of life from the arena of the world to that of the soul and quell it there, the Western to drown the tumult of the soul in action." There speaks the really wise man.

Part III. (Notes on Administration) deals amongst other things with public-houses, prostitution, the police, and housing. It is, on the whole, satisfactory to learn that Mr. Booth's observations on public-houses and on publicans place them in a less unfavourable light than that in which they are viewed by many serious reformers. He is of opinion, however, that public-houses should be under more stringent control and that the administration might well be carried out by a small committee of the London County Council, assisted by assessors. He believes that as a result new legislation would be directed to the extra rating on the increased value created by granting licences, to placing clubs under the same restrictions as public-houses, to alterations in the regulations of the hours of supply, to the avoidance of penalising drinks which contain little alcohol, and possibly to the municipal ownership of licensed houses.

Of the metropolitan police Mr. Booth gives, on the whole, a very favourable account, although he is inclined to believe that "as police-court witnesses they are too expert." A magistrate who constantly heard their evidence said that he had learnt when to distrust it. "Perhaps this is a safeguard," says Mr. Booth, "for if accepted in so critical a spirit this expert professional evidence will be taken for what it is worth and no more." On the question of housing there is much valuable information. There is a large and clear map showing the places of worship, the schools, and licensed houses in Central and East London.

Part IV. contains the Conclusion which deserves the most careful study; it is very short, occupying only 16 pages. It can neither be condensed nor summarised. It must be read as it is written. Charles Booth has done a great work for those who live and labour in London. May it in due time bear fruit.

Foods: their Composition and Analysis. By ALEXANDER WYNTER BLYTH, M.R.C.S. Eng., F.I.C., F.C.S., and MEREDITH WYNTER BLYTH, B.A., B.Sc., F.I.C., F.C.S. Fifth edition, thoroughly revised, enlarged, and re-written. London: Charles Griffin and Co., Limited. 1903. Pp. 616. Price 21*s.*

WITH the advance of analytical methods and with, also, fresh legislation on the adulteration of food, it was inevitable that a further edition of this well-known and standard work on foods should be issued. Certainly great advances have been made since Mr. A. Wynter Blyth brought out his "Practical Chemistry," a quite small volume compared with the book before us, and his treatise on "Poisons," which is uniform with it. Mr. Wynter Blyth has now availed himself of the assistance of his son in editing the work and to collaboration we may assign some new chapters, as that on the Bacteriology of Water and the Detection and Estimation of Arsenic. Much of the work of necessity has been rewritten owing to the fact that since the issue of the previous edition legislation has been extended and new matters have arisen for consideration arising out of the beer-poisoning epidemic in the Midlands. The introductory chapters on the History of Adulteration have, we think, been wisely retained, as well as those dealing with the legislation on this subject in other countries. This plan, as far as we know, has not been adopted in other works and the chapter alluded to affords very interesting reading, tracing not only the kind and degree of fraud practised in regard to food in early times but relating also the methods of detection employed. It might be anticipated that the work of the Analytical Sanitary Commmission of THE LANCET would be described in this section and it is so, the authors acknowledging the value of the work of THE LANCET, past and present, in regard to protecting the public against the adulteration of its food. The chapter on the Examination and Analysis of Water is excellent and quite up to date, but we think that the section on Alcohols and Spirits might have been extended with advantage: we can find little in it differing from that which appeared in the previous edition on whisky, brandy, and gin, yet during the past few years some important contributions on the chemistry of potable spirits have been made, notably by Allen, Schidrowitz, Hewitt, THE LANCET Special Commissions, and others. We find, by the way, in the present edition a paragraph on whisky in which the bad effects of spirits are referred to furfural. In other sections the word is spelt "furfurol." A misprint in the previous edition has also evidently escaped the authors' attention in the proof-sheet. Thus in a paragraph on the detection of aldehydes by means of fuchsine it is recommended to make up a standard solution containing 0 050 gramme per litre of acetic anhydride. "Anhydride" should, of course, be "aldehyde." The footnote on p. 398 in regard to tannin in brandy might have been left out as it is now somewhat ancient history. We still think that analysts should give more attention to the question of differentiating by chemical analysis one kind of spirit from another. As it is, if a sample of spirit is sent to the public analyst which has been purchased as brandy and yet which proves to be whisky or worse he will report it on his certificate as genuine so long as its alcoholic strength is satisfactory, and probably few analysts are aware of the chemical evidence which can be brought to bear in distinguishing a genuine grape spirit from a malt or a grain spirit.

We congratulate the authors on having brought this well-known work up to modern requirements in regard to the detection of the adulteration of food. We have expressed the opinion before that the work is of a thoroughly standard character and that it is a very valuable and trustworthy guide to the modern analyst.

Medical Microscopy, designed for Students in Laboratory Work and for Practitioners. By T. E. OERTEL, M.D., Professor of Histology, Pathology, Bacteriology, and Clinical Microscopy, Medical Department, University of Georgia. With 131 Illustrations, some coloured. London: Rebman, Limited. 1903. Pp. 362. Price 9*s.* net.

THE author of this book recognises the fact that medical works are being produced every day and that an addition to medical literature is not to be made light-heartedly. Owing, however, to the rapid growth of microscopy as an aid to diagnosis and to the fact that, in America at all events, those who graduated more than a decade ago received but scanty instruction in laboratory work, it is believed that there is a distinct need for some work such as the present volume. It is especially intended for the beginner in microscopy and for the man who has to dispense with the advantages of a laboratory or of a personal teacher. In a work which in the short space of 362 pages undertakes to treat of the technique of section cutting, staining methods, bacteriology, morbid histology, and the histology of the blood it is needless to speak of sins of omission, indeed, omission of all but absolutely necessary details becomes a virtue. A rigid selection of the best methods and the elimination of all non-essentials alone make the task possible, and even then it argues considerable courage to undertake such a work. Granted the above limitations it must be confessed that Professor Oertel has been successful in giving a clear and accurate account of his subject and one which will doubtless be of value to those for whom the book is intended. At the same time it is impossible to avoid the thought that a short time spent in a laboratory would be of extreme value even to the reader of this book.

A clear account of the microscope and of the methods of hardening, cutting, and staining tissues is followed by chapters on bacteriological methods with descriptions (which as a rule are excellent for the avowed purpose of the book) *of the principal pathogenic germs.* It seems a pity that in the section on Mycoses the illustrations should be of the common moulds, while the parasitic diseases of the hair are left unillustrated and very scantily described. The morbid histology of tumours is next treated in a section occupying some 30 pages. This portion is illustrated fully by reproductions of photographs of sections of the various tumours described. Nearly 60 pages are devoted to the study of the blood, and though the descriptions of methods and of the varieties of cells met with are good and clear it is impossible not to feel pity for the student who has to pick his way through the mazes of blood examinations without more help than this section can afford him, good though it is. The urine is decidedly well treated and the tabular statements of renal diseases with their associated urinary deposits will be very useful. The importance of knowing the total quantity of urine passed, and the futility of percentage analyses without this knowledge, are not so strongly insisted upon as English experience would warrant. A section on the examination of the sputum is good.

It is impossible not to recognise the many good points of this book, while at the same time it is equally impossible not to feel the great difficulties which lie in the way of an adequate treatment of so large a subject in so limited a space. The volume is well produced, but there is room for a little more careful "reading." Several proper names are misspelt—Ziehler for Ziehl, Marmoret for Marmorek, Schnell for Schull—while certain decimal points are missing, so that both the bacillus coli and the streptothrix actinomycosis are said to be 5 μ in diameter, while the bacillus anthracis is described as 1 μ to 5 μ in thickness, and in describing the indol reaction sodium nitrate is substituted for sodium nitrite.

Manuel de Bactériologie Clinique. Par M. FUNCK, Chef du Laboratoire de Bactériologie de l'Université de Bruxelles, Directeur de l'Institut Provincial de Sérothérapie. Second edition. With seven coloured Plates. Bruxelles: Henri Lamertin. 1903. Pp. vii.–239.

THIS work, which has reached a second edition, is a *résumé* of the course of practical bacteriology given at the University of Brussels and is also intended to serve as a handbook for medical men by means of which they may learn how to make the ordinary bacteriological examinations which are required in practice. It must be confessed, however, that as a practical manual this book leaves much to be desired, many of the instructions being singularly lacking in precise details. This is readily understood if the volume is intended to be supplemented by the demonstrations of the practical course, but the lack of detail militates against its usefulness to practitioners. A very much larger amount of space is devoted to the consideration of immunity than is usual in a work on clinical bacteriology, very nearly half the book dealing with this subject. The author justifies this by insisting on the importance of accurate knowledge in order that rational practical treatment may be employed.

The first two chapters are occupied by a succinct and clear account of Microscopical and Bacteriological Technique. The pathogenic organisms are studied in relation to the secretions or excretions in which they are usually found and the successive chapters deal with the bacteriology of pus, false membranes, sputum, and fæces. This arrangement has obvious clinical advantages, though it tends to the appearance, in the chapter on pus, of organisms such as bacillus tetani and bacillus tuberculosis, the principal function of which is certainly not that of pyogenesis. Turning to the practical side of the book and taking the serum diagnosis of typhoid fever as an example of the instruction given, we find that, though the examination of the "hanging drop" is mentioned, yet the only method described is that of macroscopic sedimentation in ordinary test-tubes requiring the use of no less than ten drops of blood. In the directions for the bacteriological examination of the blood the only method suggested for obtaining the blood is by simple puncture of the sterilised finger or ear, but blood for cultural purposes is now almost invariably withdrawn from a vein by means of a sterile syringe. There are short chapters on the examination of water (under this head the bacillus typhosus and the bacillus coli are studied), air, and soil. The book ends with a useful tabular statement of the organisms usually found in affections of the respiratory, digestive, genito-urinary, and nervous systems.

The work probably serves a useful purpose in relation to the practical course of which it is a *résumé* and certainly contains a very good account of the current views on immunity, but there is no reason why it should displace the excellent works on clinical bacteriology which are at present at the disposal of the English student or practitioner.

Bacteria in Milk and its Products, designed for the Use of Students in Dairying and for all others concerned in the Handling of Milk, Butter, or Cheese. By H. W. CONN, Ph D, Professor of Biology, Wesleyan University. With 43 Illustrations. London: Rebman, Limited. 1903. Pp. 306 Price 6*s.* net.

WE have already welcomed a work on "Agricultural Bacteriology" by this author and the present volume is characterised by the same directness of aim, practical nature, and clear separation of facts from probabilities which marked the previous book. The title-page indicates those for whom the work is intended, but in addition it will be useful to boards of health and sanitary officers who are interested in the connexion between milk and disease.

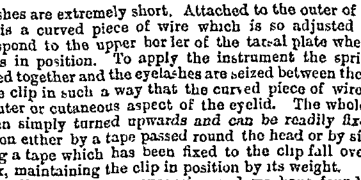
After a short preliminary chapter on the Nature of Bacteria the sources from which these organisms gain access to milk are dealt with and the means by which contamination may be kept within bounds. Keeping strictly to practical methods the author holds that with *ordinary precautions* the number of organisms in milk at the dairy can be reduced to 1000–5000 per cubic centimetre. The typical milk bacteria, and those which produce objectionable changes in that fluid, are then studied and there is a short account of the various dietetic products of the alcoholic fermentation of milk with an appreciation of their value. The changes in the number and character of the organisms of milk produced by temperature and time are described, and in Chapter V. there is a well-balanced account of the pathogenic organisms found in milk and their influence on the spread of disease, together with some useful hints on the methods to be employed in the study of milk epidemics. How the consumer of milk products is to be protected by sanitary regulations, by methods of purification, and by methods of sterilisation or pasteurisation is considered in detail. Purity of milk really resolves itself into a matter of expense and regulations are required to protect the poor. The work being designed as much for dairy workers as sanitarians a considerable part of the book is taken up by a consideration of the relations of bacteria to the processes of butter and cheese making. Curiously enough, it appears to be the oleomargarine factors who have paid most attention to the bacteriology of butter.

A final section is devoted to a short account of methods of analysis, in which attention is drawn to the conclusions which are yielded by a rough qualitative separation of the micro-organisms present into "acid producers" (lactic), gelatin liquefiers (enzyme producers), and others. Attempts to determine the absence of pathogenic bacteria except in quite exceptional circumstances are regarded as useless. The general appearance of the book is satisfactory but a reference number on page 66, line 16, is omitted and there are some very curious divisions of words allowed by the printer. This work cannot fail to be of interest and use to those who are concerned with the production, distribution, or regulation of milk and its products.

New Inventions.

A SIMPLE EYELID EVERTER.

THE recent extension of the application of the x rays to the treatment of trachoma necessitates, of course, the eversion of the eyelids during the exposure of the patients to their influence. This can be done in the usual manner, but it has the grave disadvantage that the hands of the operator are of necessity exposed also, and it is to obviate this that we have devised the simple appliance represented in the accompanying illustration. This enables one to evert the eyelids without contaminating the hands with the discharge —a distinct advantage considering the infective nature of the condition—and to maintain the eyelids in the everted position without in any way exposing the hands of the operator. It will be seen that the instrument consists of a spring ending in two jaws coated with india-rubber and curved to correspond to the curvature of the palpebral margins. These serve to grip the eyelashes and the india-rubber coating enables them to do this even in those cases in which the eyelashes are extremely short. Attached to the outer of these jaws is a curved piece of wire which is so adjusted as to correspond to the upper border of the tarsal plate when the clip is in position. To apply the instrument the spring is pressed together and the eyelashes are seized between the jaws of the clip in such a way that the curved piece of wire is to the outer or cutaneous aspect of the eyelid. The whole clip is then simply turned upwards and can be readily fixed in position either by a tape passed round the head or by simply letting a tape which has been fixed to the clip fall over the vertex, maintaining the clip in position by its weight.



The clips are very inexpensive and we have found that they are very comfortable to the patients. The india-rubber can be readily renewed and the whole can be easily sterilised by boiling. They have been made for us by Messrs. Harry Cox, Limited, of Cursitor-street, from whom they can be obtained.

A. D. REID, M.R C.S. Eng,
Radiographer to King's College Hospital and to the Evelina Hospital for Sick Children.
ARTHUR EDMUNDS, B S. Lond., F.R.C.S. Eng.,
Sambroke Surgical Registrar, King's College Hospital.

THE BRITISH MEDICAL ASSOCIATION

MEETING AT SWANSEA.

THE SECTIONS.

MEDICINE.

Friday, July 31st.

Dr. R. J. M. **Buchanan** (Liverpool) opened the discussion on

Susceptibility and Infection.

After tendering his apologies for any shortcomings in his remarks on account of the shortness of the notice received he said that he would approach the subject mainly from its clinical and practical aspect. He considered natural resistance and its opposite susceptibility to infection to be distinct potential and vital phenomena. Immunity might be defined as resistance to a disease and there was a difference between immunity to the bacilli and to their toxins, just as there were pure bacterial infections and bacterio-toxic infections, though no hard-and-fast line could be drawn between them. The phagocytic theory of Metchnikoff and its readjustment to more recent theories were discussed. Reference was made to the action of leukæmic blood on bacteria. In natural resistance the alexins were to be regarded as protective agents by virtue of the dissolution of organised foreign substances which they normally effected, whether they were foreign red blood corpuscles or bacteria. Increase of resistance, general or local, mainly depended upon hyper-leucocytosis and methods of increasing natural resistance by production of hyper-leucocytosis were referred to. The natural resistance against toxins was regarded as a means by which the alexins and phagocytic cells were enabled to act protectively. In reference to acquired susceptibility Dr. Buchanan emphasised the importance in medical practice of recognising the part played by such adverse conditions as starvation and bad diet, exposure to heat, cold, and moisture, fatigue, and diseased conditions as general interferences with resistance. The importance of recognising the rôle of mixed infections was discussed, with special reference to pulmonary tuberculosis. Professor Welch's hypothesis of reciprocal infection provided material for much serious thought. Recognising in cultures of pathogenic bacteria intracellular and extracellular poisonous substances Dr. Buchanan asked—Were the bacteria while manufacturing these toxins living under conditions normal to them? Did the culture media contain the very substances which provoke the bacteria to form such toxins and immunising bodies? Had they any certain proof that bacteria living in conditions natural to them produced any such toxins at all? The possibility of reciprocal infection between different species of bacteria was pointed out. Assuming the possibility that under conditions natural to them bacteria did not produce poisons, Dr. Buchanan suggested that in a case where an animal was naturally immune to a specific bacterial invasion there would be nothing in its tissues or body fluids which affected the bacteria in any way. On the other hand, should any alteration of these tissues and fluids have taken place before invasion, conditions arose which acted upon the bacteria to make them offensive factors—in fact, the determination of the disease was dependent not upon the invasion of the bacteria alone but upon the action upon them of the tissues and fluids of a body antecedently deranged. Or both host and bacteria might be in an abnormal state prior to their meeting. When the question as to how bacteria brought about disturbances of the body metabolism was considered it should also be remembered that bacteria did not always effect this change and that disturbances of metabolism had probably existed previously and might have been a causal agent. The immunising power of human milk was referred to and it was suggested that the susceptibility to tubercle in hand-fed infants might thus be accounted for, the cow being a susceptible animal. In conclusion, Dr. Buchanan discussed the question of racial and individual resistance and susceptibility relative to inheritance.

Dr. A. **McPhedran** (Toronto) took exception to the statement that the natural resistance varied with the natural vigour of the individual. Were not strong, vigorous young men very prone to contract enteric fever? He would also like to ask Dr. Buchanan how the well-known efficacy of the inoculation of erysipelatous streptococci as a treatment for malignant disease was to be explained.

Dr. D. C. **McVail** (Glasgow) referred to patients apparently in the highest bodily vigour attacked with tuberculosis and other diseases. Might it not be a chemical change which constituted susceptibility as in the culture media used in the laboratory? A closer study of the culture bases on which bacteria throve might in the future elucidate this problem.

Dr. G. **Parker** (Bristol) communicated

A Case of Bronzed Diabetes.

The patient, a man, aged 65 years, suffered from diabetes for five months before his death from coma. During life definite greyish-brown pigmentation was noticed on his face, trunk, and limbs, but not on the mucous membranes. The urine did not average more than 50 ounces daily and before the onset of coma it contained no acetone or diacetic acid, but about 5½ per cent. of sugar. At the post-mortem examination besides pigmentation of the skin and muscles there was very marked hypertrophic cirrhosis of the liver and to some extent of the pancreas and spleen. All these organs, as well as the lymphatic glands, were so infiltrated by a pigment containing iron that they were of a deep brown colour, changing to a brilliant blue after treatment with hydrochloric acid and ferrocyanide of potassium. Sections showing these changes were exhibited in the room and the liver and pancreas were placed in the museum. The intestines after removal quickly turned to a dusky metallic grey. This disease was at first thought by Hanot, Marie, and others to be a complication of diabetes, but the view was gaining ground that it was a form of toxic cirrhosis in which hæmoglobin was changed to hæmosiderin and retained in the body, while diabetes came on in a proportion of the cases either from irritation of the suprarenals or from cirrhosis of the pancreas.

Dr. **McVail** read a paper on

The Treatment of Uræmia by Spinal Puncture.

Œdema in acute renal affections developed suddenly and was universal and the connective tissue in the brain was involved in the general œdema. There was thus produced a condition of increased intracranial over-pressure, as the cranium was an undilatable chamber. Convulsions and coma occurring in connexion with albuminuria had very generally been regarded as the effects of uræmic poisoning, but Dr. McVail had for some years been in doubt as to the truth of this poisoning theory. In his view they were due to the increased intracranial pressure and if the symptoms of convulsions and coma in renal disease were due to intracranial pressure that pressure would obviously be lessened by puncture and drainage of the spinal arachnoid space. In 1900 and again in the present year of 1903 he had had the opportunity of practically determining this question. In the first of these years a patient with acute albuminuria and œdema, after severe intracranial pain followed by convulsive attacks repeated during 30 hours, had become almost blind, and notwithstanding free perspiration by hot-air baths and pilocarpine he became comatose The operation of spinal puncture was performed at Dr. McVail's request by Dr. D. N. Knox. The spinal fluid fell in drops from the cannula for three-quarters of an hour and then the cannula was withdrawn. In all about six drachms of fluid escaped, the patient being entirely unconscious and no anæsthetic being required. Within four hours the patient began to regain consciousness and his sight commenced to return. He slept a natural sleep during the night and awoke in the morning entirely free from pain or mental dulness or confusion and with perfect vision. No more fits occurred. The urine rapidly increased in amount, the albumin rapidly diminished, the œdema disappeared, and he left the hospital some weeks afterwards with only a trace of albumin present in the urine. The second case was that of a man in whom albuminuria had quickly developed with moderate œdema of the surface. In a few days he had become mentally confused and he was still mentally confused when he was taken to the Royal Infirmary, Glasgow. His urine contained a large amount of albumin. Hot-air baths and pilocarpine produced free perspiration, but without benefit to his cerebral state, and 36 hours after admission the comatose condition was deep. Dr J. Patrick performed spinal puncture and fully an ounce of fluid escaped. Again, as in the first case, at the end of *about four hours consciousness began to return and he made* a good recovery The result of the spinal puncture in these two cases proved, in Dr McVail s opinion, that the pain, the convulsions and the coma of acute albuminuria were due in many, if not in all, instances to the sudden increase of intracranial pressure and not to uræmic poisoning of the nerve centres They further proved that this increased intracranial pressure might, in at least some instances, be effectually relieved by spinal puncture

Dr T N KELYNACK (London) and Mr SYDNEY R WILLIAMS (Bristol) communicated a paper on

The Comparative Value of Oral and Rectal Temperatures in the Study of Pulmonary Tuberculosis

The conclusions arrived at were based upon 17 420 observations in 300 different cases, in all stages and of every variety of tuberculous disease of the lungs It was shown that in a healthy adult during rest the rectal temperature was normally a little less than 1° F higher than the oral, but after exercise the rectal temperature was raised from two to three degrees. After a man had played an hour at lawn tennis, for instance, the rectal temperature would rise from 99° to 101 4°, though in the same circumstances the oral temperature had only risen from 98 4° to 98 6° These normal or physiological variations in the temperature in the rectum deserve careful attention In 38 per cent of the patients examined the rectal temperature bore no constant relation to the oral In 11 3 per cent the rectal reading maintained a more regular range than the oral In 1 3 per cent of the cases the rectal temperature was constantly from one to two degrees above the oral record Generally speaking, the discrepancies between oral and rectal temperature had been most apparent in patients with a comparatively slight degree of pyrexia, while they had more closely corresponded when a conspicuous and persistent degree of pyrexia existed. The results of the investigation seemed to warrant the following conclusions 1 The temperature taken in the mouth during rest formed a trustworthy guide in the management of tuberculous cases under conditions of sanatorium life. 2 The temperature taken in the mouth during or shortly after, exercise could not be considered trustworthy unless accompanied by such precautions as militated against their general practical applicability 3 The temperature taken in the rectum during red higher than in the mouth afford any special assistance in [illegible] cases 4 The temperature taken in the rectum during, or shortly after, exercise in both healthy and tuberculous subjects registered a temperature considerably higher than that in the mouth, and whilst in the non tuberculous the return to normal was more rapid than in the tuberculous no special advantage for the latter appeared to accrue from this method

Dr CHOWRY MUTHU (Wells) read a paper on

The Treatment of Pulmonary Tuberculosis by Formaldehyde

The methods by which he had administered the drug were (1) by an inhaler, using a mixture of 40 per cent formalin one part, chloroform, one part, rectified spirit two parts with a few drops of liquor ammoniæ to neutralise the pungency, (2) by vaporisation, (3) by intravenous injection as suggested by Dr Robert Maguire, and (4) by electricity using Francisque Lôtte s method of transfusing formaldehyde by static currents of electricity The first and second of these methods were advocated as shortening the duration of the treatment As to the third and fourth methods it would Dr Muthu said, be premature to speak of any positive and definite results at present as the trials had not yet been sufficiently extended

Dr BUCHANAN remarked that before coming to a conclusion as to the value of formaldehyde he would like to compare cases which had been treated solely by this reagent with others treated in other ways

SUBSECTION OF ELECTRO THERAPEUTICS

WEDNESDAY, JULY 29TH

Dr H. LEWIS JONES (London), the President of the subsection, opened a discussion on

The Treatment of Malignant Diseases by Electrical Methods

He said It gives me great pleasure to open the proceedings of this subsection because I am sure we all feel that the occasion is one of note in the history of medical electricity in this country The establishment of a subsection for electro therapeutics under the auspices of the British Medical Association marks a stage in the advance of the subject in public interest and is a source of gratification, I feel sure, to all who have the interest of medical electricity at heart and to all those whose patient work for years past has helped to lay a firm foundation for the superstructure of the future I trust that this gathering may be the first of a long unbroken succession of meetings at which the inevitable advances of the science of electricity with their equally inevitable applications to medical science may be described and criticised, to receive judgment in accordance with their deserts The subject which is down for our consideration is one of the highest importance All over the civilised world just now men's *minds are being turned with fresh energy towards the* object of finding some means which can be used to check the advances of that group of disease which we know as malignant disease There is a feeling that in some way or other a cure might be found in spite of all failures of the past. In particular the newer discoveries of science are being examined by medical men and when any fresh fact seems to offer a clue the path which it indicates is being followed up minutely Medical men have always shown themselves ready to make a practical application of the discoveries of science Take, for instance the applications of the x rays The progress in this section has been almost purely a medical matter It is the medical profession which has provided the stimulus for the elaboration of x ray machinery and methods and has accounted for the astonishing development of Professor Roentgen s discovery So too with the alternating current supplied in towns for electric lighting No sooner was this type of current supply available than its therapeutic possibilities were being examined and applied by medical men, with the result that it is now a thoroughly recognised method of medical treatment and is filling its own proper corner in the field of electro therapeutics, so also with the high frequency group of phenomena the phenomena of condenser discharges as in the Leslie Miller lamp, and the phenomena of radio activity—that newest development of chemical science. The grievous nature of cancer and the distress of mind from which its victims suffer make it a subject which must be discussed without enthusiasm The discredit which has attached to the cancer curing impostors of the past will deservedly be ours unless we are particularly careful to keep rigidly within the bounds of observed facts In a semi public assembly like the present one we must be excessively careful to avoid anything like over statement of the case The line which I believe we can most advantageously follow to-day will be that of relation of cases and the discussion of practical points—such as the best sort of tube the best time or exposure the number of applications which has been found most suitable, and so on First let us examine the observed facts upon which there is now a general agreement of opinion among x ray workers—namely, (1) that in rodent ulcer a satisfactory result may be often observed, (2) that healing of an ulcerated cancerous surface has been observed in a certain portion of cases, (3) that relief of pain in cancer is a fairly common experience, and (4) that superficial nodules undoubtedly cancerous in nature will sometimes decrease notably in size under x ray treatment This is the groundwork upon which we hope to be able to build but the edifice is not yet built, nor do we even know whether we shall ever advance much further Having reached our present position we are searching I might say groping in the dark for a fresh clue to enable us to progress another stage What direction shall we take? Shall we use hard tubes soft tubes or medium tubes? Shall we operate our tubes with the anti cathode red hot or cool? Shall we have the tube close to the part or remote from it? Do we desire a reaction of dermatitis or do we need to avoid it carefully? No one knows, though some of us have opinion Only a sifting of cases and a comparison of results will in time teach us whether these points matter or not If we have no successes to relate let us tell of our failures and try to learn from them The successful treatment of rodent ulcers by the x rays is now sufficiently established for us to leave it on one side at present I do not mean that there is no more to learn about this particular disease but that the points not yet worked out are such as may be left for the present to individual investigators. I would suggest, therefore, that to day we should limit our remarks to cases of undoubted sarcoma or carcinoma. If it were possible to do so we would choose to begin in the case of carcinoma with simple superficial epithelioma, as for example, epithelioma of the lip in its earliest stages. If in such cases it could be satisfactorily established that a complete disappearance of the growth followed the treatment, it would be reasonable to advance to the more difficult problems of deeper growths. Unfortunately, these are just the cases which we cannot as yet obtain. Naturally the surgeon who feels that an immediate cure can be secured by a prompt operation is reluctant to run the risk of sacrificing his patient's chances by any procedure which involves delay. His attitude is not likely to change until it can be shown that the results of treatment by the x rays are as good as those now obtained by excision. That is the position of affairs to-day and the only material which is available for the study of the effect of the x rays upon malignant disease is among cases which are too extensive or too deeply seated for the surgeon to be able to touch them. Naturally this complicates matters a good deal and adds very greatly to the difficulties of the position. In spite of these difficulties cases have been recorded which show that the progress of epithelioma can be profoundly influenced by the application of the x rays. Even if we pass over partial successes *and consider only such as are complete we find some* satisfactory evidence to support us. Macintyre of Glasgow has recorded a case of epithelioma which filled the nasal cavity; eight months later the whole neoplasm had disappeared under x-ray treatment. The diagnosis of the case was confirmed by microscopical examination. In looking through the published records of the use of the x rays in cancer one cannot help feeling surprised to find how few of the alleged successful cases have been so recorded as to carry to those who read a reasonable conviction of success, and this, too, in spite of the fact that numbers of people are working at this subject, and scores, if not hundreds, of cases have been treated. Half a dozen cases of unmistakeable cure of undoubted cancer, if minutely reported, would be worth more just now than any number of vague statements about partial improvement, favourable effects, and the like. The more one examines the published cases the more suspicious one becomes. In most of them there is some flaw in the evidence. Either the diagnosis is uncertain or the patient is not more than partially relieved at the time of writing or he has been so unfortunate as to die from some intercurrent disease. It is greatly to be wished that all medical men who have recorded favourable cases will periodically supply further notes of the later progress of their patients. In short, while there is a quantity of evidence to support the contention that the x rays act beneficially in malignant disease the amount of evidence to show that cures have resulted is lamentably meagre. What can be the explanation of this? Here is an agent which very commonly gives relief to some of the symptoms produced by a malignant growth and yet fails to give as much relief as is really required. Is it because of some defect in our technique, or is it because the cases subjected to x-ray treatment are ill chosen, or, finally, is it from some inherent defect of the method of a fundamental kind? This is the crux of the situation. First as to technique. Have we yet to discover that some tubes only emit the right kind of x ray? Have we to use our tubes differently? or do we fail from insufficient perseverance? The nature of the tube, the degree of penetration of the rays which it gives off, the proximity of the tube to the affected part, the production of a reaction or not, are all points on which further knowledge is wanted. Already there is a divergence of opinion as to the need for a dermatitis or not, for while some observers think that the good effect is in proportion to the amount of dermatitis, others hold a quite opposite view. Secondly as to the selection of cases. Most of us will agree that the cases hitherto submitted for x-ray treatment have been of the most unpromising character. Most, if not all, of them have been of a kind which were already too advanced to be other than practically hopeless from the first. And whereas the failure has usually been from the reappearance of the disease in a vital organ remote from its original seat, the application of the x rays has so far justified their employment by improvements at the place to which they were applied. Thirdly, as to inherent defects in the x-ray method. It may be that all our efforts will be in vain because of this; but until the method has been tried for simple cases at an early stage we cannot abandon our attempts. In my opinion the proper course to adopt would be to start the x-ray treatment as soon as possible after the removal of the primary growth by the surgeon and not to wait until recurrences have seriously spoiled the chances of success. I would avoid all masking of the surrounding parts by impervious screens for fear lest the screens should shield some foci of disease. It is probable that the use of lead screens have contributed a good deal to the failures of the past. I would use a medium tube and would prefer to operate with a hot anti-cathode. I would avoid dermatitis by arranging the exposures suitably and I would continue the treatment with occasional breaks for three, four, or five months. In conclusion, it is necessary to speak of other proposed electrical methods—namely, the high-frequency method and the use of the static machine. Both of them have been tried and both have had some slight success to show. In both methods there is a common factor—namely, the presence of cathode rays—and it seems to me possible that these may require further examination. Curiously enough, radium has lately been tried for the relief of cancer and cases of its favourable action have been mentioned. The rays emitted by radium are of two kinds, one apparently identical with the x rays and one with the cathode rays, and it may be that the combination of the cathode rays with the x rays has *some special advantage.*

Mr. J. F. HALL-EDWARDS (Birmingham) continuing the discussion said that the failures so far noted were largely due to the extremely unfavourable character of the cases submitted to the treatment. He had no doubt at all that cases of early epithelioma of the surfaces of the body could be cured by the x rays in a satisfactory manner. As to internal cases he had treated a case of cancer of the rectum by applications to the sacral region, and his patient was alive still after three years had elapsed and the growth had diminished in size. He had often noticed that with the appearance of a dermatitis the patient began to feel better. He would like to know whether the use of the x rays did harm in some cases by leading to the liberation of toxins during the process of regression of the tumours under treatment. He agreed in preferring a medium tube with a hot anti-cathode. He insisted less now than he had formerly done on the necessity for producing a sharp dermatitis.

Mr. CHISHOLM WILLIAMS (London) had obtained good results from the use of the high-frequency machine. His method was, he believed, very important if successful results were to be obtained by that apparatus. He used an electrode of glass tube so exhausted as to emit x rays. Its vacuum could be judged by seeing whether the wall of the tube emitted a green phosphorescence. If it did this x rays were being produced. There were present, therefore, x rays, cathode rays, ultra-violet light, and general electrification. The tube could be put in contact with the patient and x-ray burns were not at all likely to result. He had obtained marked relief in many cases but had no complete cure to record as yet.

Dr. C. H. ALLFREY (St. Leonards) suggested that drugs might be employed together with the electrical treatment; possibly iodide of potassium might be useful to remove the products of the breaking down of the growths.

Dr. HORACE MANDERS (London) had tried experiments with the high-frequency current, using vacuum electrodes of blue glass, particularly of cobalt glass. He advised the study of the pulse tracings during and after treatment, also a careful examination of the urine.

Dr. LOVELL DRAGE (Hatfield) had found benefit in many cases of malignant disease from the use of cinnamate of sodium as a hypodermic injection; he thought that this method might give improved results if combined with the electrical treatment. The effect of cinnamate of sodium had been surprisingly good in some of his cases.

Among other matters touched on was Radium and its Possible Therapeutic Uses. It was pointed out that radium had one valuable quality which would help in proportioning the times of exposure—namely, that its radiations were uniform in strength.

The PRESIDENT, in closing the discussion, said that several valuable points had been elicited by the debate. He believed that the vacuum electrode used with a high-frequency coil might develop into a useful instrument. The diffused x rays offered some advantages, particularly in the diminished risk of x-ray burns, and it was highly probable that the coexistence of cathode rays around such a tube might be useful. He had treated a patient after an operation for the removal of a recurrent carcinoma in the glands of the neck with the object of preventing a further recurrence. After three months of mild x-ray treatment the scar of the operation wound began to feel hard and it was again excised. A microscopical examination showed the presence of a few cancer cells, much fibrous tissue, and some extravasated blood corpuscles, and the pathologist who reported on the specimen was doubtful as to its exact character. The specimen removed at the preceding operation was of typical carcinoma, rich in cells. The x rays seemed, therefore, to have influenced the growth and to have altered its character in a favourable direction. He thought that a more vigorous application of the rays might have been successful in preventing the reappearance. He hoped that the subject of x-ray treatment for malignant disease would again come before the Subsection of Electro-therapeutics in 1904 and that further advances might by that time have been achieved.

THURSDAY, JULY 30TH.

Mr. CHISHOLM WILLIAMS opened a discussion on

The Treatment of Tuberculous Diseases by Electrical Methods.

He said that he had treated 43 cases of pulmonary tuberculosis by high-frequency methods. After two years 40 patients were living, though one was now very ill with tubercle of the urinary tract. An examination of the sputa showed an increase of bacilli for a time followed by a decrease. It was also common for the patients to have a distinct rise of temperature for a few days. As soon as this subsided the patients showed manifest improvement. In tubercle of other regions of the body the results at present were uncertain. In lupus the high-frequency treatment by the high vacuum glass tube was very satisfactory.

The PRESIDENT having pointed out that the discussion might be conveniently arranged under the heads of pulmonary tuberculosis, tubercle of other organs, and lupus, most of the later speakers dealt mainly with lupus.

Dr. P. S. ABRAHAM (London) expressed a preference for the x rays in the treatment of lupus and pointed out the peculiarity that cases apparently identical might behave quite differently under apparently identical treatment.

Dr. J. S. BOLTON (Nottingham) recounted his experiences in pulmonary tubercle and thought that the high-frequency treatment had a bad effect if applied to subjects in whom a hectic temperature existed.

Dr. V. RUTHERFORD (London), Dr. R. B. McVITTIE (Dublin), Dr. H. H. HULBERT (Bexhill-on-Sea), and Dr. JOHN HADDON (Denholm, N.B.) also spoke.

Mr. HALL-EDWARDS read a paper on Some Points in X-ray Therapeutics and Mr. W. K. WILLS (Bristol) showed a Modification of the Leslie Miller Lamp, in which the iron discharging points were altered to carbon with iron cores.

FRIDAY, JULY 31ST.

Dr. J. C. FERGUSSON (Great Malvern) read a paper on High-frequency Currents as a Remedy for some Forms of Deafness.

Dr. DONALD BAYNES *(London)* read a paper on the Treatment of Painful Amputation Stumps by Electricity.

Dr. W. S. HEDLEY (London) contributed a paper on Practical Muscle-*testing which was read by the Secretary.*

Dr. BOLTON opened a discussion on X Rays in the Diagnosis of Thoracic Disease.—Dr. W. H. I. SELLERS (Preston), Dr [illegible] an [illegible] an [illegible]

OBSTETRICS AND GYNÆCOLOGY.

FRIDAY, JULY 31ST.

Mr. J. H. TARGETT (London) opened a discussion on

The Diagnosis and Treatment of Tuberculosis of the Uterus and Adnexa.

He said that *it was not until 1886 that attention was drawn* by Hegar to the importance of this affection; in 1894 Whitridge Williams gave a good account of it and at the Fourth International Congress of Obstetrics and Gynæcology held in Rome in 1902 the subject was fully discussed. In the post-mortem records of Brompton Hospital it was shown that in 6 per cent. of tuberculous females there was disease of these organs. The number of cases in which the disease was primary and limited to the genital organs was much smaller. The modes of infection were: 1. By the blood stream, the seat of original infection being in the lymphatic glands, particularly the bronchial. The tubes were readily infected. 2. By the peritoneum, either from general miliary tuberculosis of the peritoneum or from localised disease due to ulceration of [illegible] fluids in the peritoneal ca[illegible] through the abdominal ost[illegible] found in 50 per cent. of the cases of tuberculous peritonitis. 3. By direct infection from the neighbouring organs—i.e., the ileum, the rectum, and the bladder. 4. From sexual intercourse; this could not be denied, though it was very rare. Tuberculosis of the glans penis was excessively rare and the infection must come through the semen. The forms of tuberculous disease met with were: 1. Acute [illegible] pyosalpinx might develop. 2. Caseous salpingitis. 3. Tuberculous pyosalpinx. The peculiarities of this form of pyosalpinx were (1) that the fimbriæ were present; (2) the contents were honey-like and often sterile bacteriologically; and (3) there was absence of *adhesions and in consequence* twisting of the pedicle sometimes occurred. Tuberculosis of the body of the uterus might be diffuse miliary and non-*ulcerative, or granular, friable, and caseous; or there might* [illegible] history, particularly with reference to any tuberculous disease, was very important. The absence of any apparent cause was suggestive; thus pyosalpinx in the virgin was almost always tuberculous. It was formerly taught that amenorrhœa was present, but further experience had shown that this was not so. Dysmenorrhœa was a common symptom. As regarded pain it might be stated generally that this was not present unless other organisms were associated with the tubercle bacillus. Large pyosalpinx without pain, especially without recurrent attacks of pain, was usually tuberculous. When the disease affected the body of the uterus there were bacilli in the discharge or in curettings, but in about 1000 specimens from curettings which he had examined he had found tubercle in only seven. *In the treatment of the* disease laparotomy was very beneficial. When the operation was performed for tuberculous peritonitis and thickened tubes were found *these should be removed*; but he had seen some cases where rapidly fatal results followed interference, in one case in 12 hours and in another in 24 hours, and he doubted the *wisdom* of removing very adherent and caseous tubes, though there was no doubt of the advisability of removing tuberculous pyosalpinx. At the close of his remarks Mr. Targett gave a lantern display of a series of 18 very fine photographs of specimens of tuberculous disease of the uterus and adnexa.

Dr. J. A. C. KYNOCH (Dundee) then read a paper on

Primary Tuberculosis of the Uterus (Cervix).

There were, he said, three forms: (1) ulcerative, (2) miliary, and (3) papillary. The last extended on to the vaginal portion; there was no friability but the growth bled readily on examination. There was menorrhagia or amenorrhœa, the former *occurring* in the early cases and the latter in later ones. Hysterectomy was performed, curetting not being sufficient on account of the possibility of infection of the uterus.

Dr. ARNOLD W. W. LEA (Manchester) read a paper entitled

Five Cases of Tuberculous Disease of the Tube treated by Operation.

He said that the diagnosis of removed specimens should never be made without a microscopical examination, as nodules having a naked-eye resemblance to tuberculous nodules were sometimes met with in other conditions. In two of his cases no other part of the body was affected; in only one was the ovary affected. The symptoms included pain which was a marked feature; the effect on menstruation varied. It was never possible to rely on the presence of bacilli in [illegible] important [illegible] temperat[illegible] developm[illegible] of the operation was [illegible] to ligature by sections across the broad ligament, and afterwards to suture the peritoneum over. If drainage was used it should be per vaginam.

Dr. **HERBERT SNOW** (London) thought that congestion of the pelvic organs produced by corsets favoured the development of tubercle. He advocated milder methods of treatment than hysterectomy.

Dr. F. W. N. **HAULTAIN** (Edinburgh) said that in operating for tuberculous peritonitis they should pay particular attention to the tubes. In regard to the diagnosis of tuberculosis of the tubes dysmenorrhœa was the most constant symptom. He narrated a case of tuberculous disease of the cervix and showed a drawing of the condition. The patient, a single woman, *virgo intacta*, had had a discharge for seven years. She had a peculiar soft growth of the cervix which was not bleeding on examination but had a bluish colour. Supravaginal amputation of the cervix was performed and on microscopic examination the growth proved to be tuberculous.

Dr. E. J. **MACLEAN** (Cardiff) narrated a case of tuberculosis of the tubes in a patient, aged 34 years, who had been married four and a half years and was sterile. She had suffered for four months from pelvic pain, dyspareunia and definite pain referred to the umbilical region, menorrhagia, and leucorrhœa. There was a swelling in the pouch of Douglas. At the operation both tubes were found studded with tubercles and containing caseous matter. The adnexa were non-adherent. The right ovary contained a cyst of the size of a walnut. Both the tubes and the ovaries were removed and the patient became strong and gained flesh after the operation.

Dr. C. R. **STRATON** (Salisbury) narrated a case of tuberculous disease of the cervix and the vaginal wall apparently due to infection from the patient's husband who was suffering from renal tuberculosis.

Mr. **TARGETT**, in reply, said that the x-ray treatment was not likely to do good in tuberculous disease of the cervix, as all specimens showed deeply placed nodules. He did not advise removal of the uterus with the tubes. It was doubtful whether the pure tubercle bacillus was a pyogenic organism, and when pus was present he would always suspect that other organisms were present. He had met with two cases of tuberculous peritonitis in which tubal gestation had occurred.

Dr. A. H. N. **LEWERS** (London) communicated a paper (which was read by the Vice-President) entitled

A Case of Hairpin in the Uterus discovered by the X Rays.

The patient went to the London Hospital and said that she was pushing in the hairpin in order "to open an abscess" when it disappeared. On examination there was some blood-stained discharge but nothing could be felt of the pin. The uterus and the bladder were examined by the sound with negative results. A radiograph taken by Mr. **HANNAN** showed the hairpin distinctly lying with its points downwards. Under anæsthesia the cervix was dilated with Hegar's dilators and each point of the hairpin was seized with a Spencer Wells forceps and the pin was extracted. There was also found a mass of placental tissue of the size of a walnut but no fœtus. The patient became very ill after the operation, having a rigor and a temperature of 106° F. Subsequently pelvic cellulitis and suppuration in the left thigh developed, the latter necessitating incision. An incision was also made into the vaginal roof and pus was evacuated. Ultimately, however, she completely recovered. Reference was made to the literature of the subject of foreign bodies in the uterus. Negebauer had recorded 74 cases and of these 16 were due to hairpins. This was the first case recorded in which the diagnosis had been made by the x rays.

A vote of thanks to the President (Professor W. Stephenson (Aberdeen), proposed by Dr. **HEYWOOD SMITH** (London) and seconded by Dr. F. J. **MACAN** (London), concluded the proceedings of the section.

STATE MEDICINE.

THURSDAY, JULY 30TH.

Dr. **JOSEPH GROVES** (Isle of Wight) contributed a paper upon

Security of Tenure for Medical Officers of Health

in which he discussed the anomalous position of the provincial medical officers of health and advocated for them the same security against capricious dismissal or non-re-election as that which had already been conceded to the metropolitan and the Scottish medical officers of health and to the Poor-law officers in England and Wales. He quoted the opinions of many Members of Parliament on the subject, including that of Sir Walter Foster who, when Parliamentary secretary of the Local Government Board, said that the Board considered appointments for short periods and precarious tenure injurious to the public health.

Mr. **HERBERT JONES** (Hereford) pointed out that it was principally through the report of the medical officer of health that the Local Government Board could ascertain whether the Public Health Acts were being properly administered and there was a distinct Gilbertian humour in the readiness with which a medical officer of health could be got rid of by a defaulting sanitary authority whose inactivity he had merely mentioned in his annual report.

Dr. F. J. H. **COUTTS** (Blackpool) and Dr. A. E. **MOIZ** (Gower) agreed with the views of the previous speakers and the **PRESIDENT**, Dr. J. C. **MCVAIL** (Glasgow), said that it must be extremely difficult to produce an argument in favour of the existing conditions. The medical officer of health being constantly in opposition to someone needed security far more than did the Poor-law medical officer.

FRIDAY, JULY 31ST.

Dr. F. G. **BUSHNELL** (Plymouth) contributed a paper on

Ministries of Public Health

in which he advocated the establishment of a Ministry of Public Health based on the expanded medical department of the Local Government Board in coöperation with the General Register Office and having associated with it a consulting body of eminent representative members of the medical profession, including the Presidents of the Royal Colleges of Physicians of London and Surgeons of England. He thought that the Minister at the head of this new department would best serve the interests of public health if he did not go out of office with every change of the Government and was summoned only to those meetings of the Cabinet which were concerned with the work of his department.

Mr. H. H. **TIDSWELL** (Cardiff) thought that general practitioners might do more in furthering public health questions among their working-class patients. He would like to see more medical men appointed as assistants to medical officers of health.

Dr. **GROVES** spoke of the non-appreciation of the work of the Local Government Board in high quarters and said that medical officers of health were handicapped by an insufficiency of inspectors.

Mr. H. **D'ARCY ELLIS** (Stourbridge) thought that the public health service might be organised on the lines of the Factory Department of the Home Office which had done remarkably good work since Dr. B. A. Whitelegge had been chief inspector. He was of opinion that medical officers of health did not receive that support from the Local Government Board which they were entitled to expect.

The **PRESIDENT** said that the question of the appointment of a Minister of Public Health had been before the country for at least 20 years and there was no doubt that inquiry into the public health administration of England and Wales was necessary in view of the introduction of a new Public Health Bill before very long.

Mr. **TIDSWELL**, in introducing a discussion on

Physical Degeneration in Children of the Working Classes,

said that his object was to draw attention to certain physiological influences which, he considered, were responsible for the nervous restlessness and waywardness so characteristic of the children attending public elementary schools. There was, in his opinion, some factor having a bad influence on the health of children which did not exist before the Education Act of 1870 came into force. The system of cram was turning children into talking machines, and in injuring their reasoning powers it was both demoralising and degrading, and was calculated to render the judgment unstable and capricious and to interfere seriously with the mental and moral equilibrium. He advocated the entire abolition of corporal punishment in schools and urged the systematic inspection of all schools by a medical officer attached to each school who should see every class as it assembled with a view to detect infectious and other diseases in their early stages and who should examine the eyesight, the teeth, the hearing, and the general condition of the children and should visit any pupil at home in case of sudden illness.

Dr. **DAWSON WILLIAMS** (London) said that they required a definition of "physical degeneration" and asked whether the conditions which produced physical degeneration were more active now than they were formerly, for there was not any statistical evidence that the amount and degree of degeneration in the population were increasing. The practical question appeared to be whether the factors which tended to prevent adequate physical development could be removed. He hoped that the decline in the birth-rate would not be mixed up with the question of deficient physical development, for degeneration might begin in utero, and attention should be given to safeguarding the health of the mother during pregnancy. If there was an increased degeneration it might be due to the altered forms of food which were partaken of in towns and whether the use of starchy foods for infants had increased or not it was certainly excessive He believed that the defects in the diet of infants caused a condition of defective nutrition which accounted for not only physical mal-development but imperfect or retarded cerebral development which was the cause of what was called over-pressure. He thought that it was a mistake to use the terms "mind" and "brain" as interchangeable, for the mind could not be tired but the brain when tired was obliged to rest. He agreed with Mr. Tidswell that medical inspection of schools was desirable but he doubted whether it would be proper to follow the children to their homes

Mr. J. M. MACKENZIE (Kirkby-in-Ashfield) thought that physical degeneration was partly acquired and partly transmitted. He was of opinion that medical men could not deal with the question alone but must call to their aid both the parson and the schoolmaster.

Mr. JOHN STRACHAN (Dollar) protested against children being required to do a large amount of work at home in addition to their lessons at school and pointed out that those who did the best at school often had a larger proportion of work at home

Dr. H. W. LANGLEY BROWNE (Dudley) considered that the medical profession were to blame in not calling the school *master more often to their aid He did not think that the* medical officer of health or the medical officer to a school should visit children in [illegible] the alien immigration was [illegible] ough he considered that the [illegible] was the food question.

Dr GROVES looked to syphilis as one of the greatest causes of physical degeneration and deplored the repeal of the Contagious Diseases Acts.

The PRESIDENT said that if physical degeneration were so pronounced as had been maintained it would surely have had some effect upon the death-rate, whereas the death rate had gone down. He considered that children should be allowed to grow up more naturally, for they were often living and breathing in places and under conditions which were deleterious to their health, although those conditions could be altered at little or no expense. He approved of the medical examination of children in schools.

Mr. W. JONES MORRIS (Portmadoc) contributed an exhaustive paper upon

The Housing of the Working Classes in Small Municipalities

in which he detailed the action which had been taken in the town of Neath for the provision of workmen's houses He urged the erection by municipalities of model houses which should act as types for the private builder to follow

The lateness of the hour prevented any discussion upon this paper.

PSYCHOLOGICAL MEDICINE

WEDNESDAY, JULY 29TH

Proceedings in this section were opened by an Address [illegible] IONS which was pub [illegible] p 366 [illegible] logist to the Scottish Asylums, then opened a discussion on

The Pathology of General Paralysis

He stated that the pathogenesis of general paralysis was still unknown with anything like accuracy and that so long as this was so they had no right to conclude that the disease was incurable. The view that general paralysis of the insane was essentially syphilitic in origin, though held by the majority of neurologists at the present day, had never been proved; it was no more than a hypothesis Against the essentially syphilitic origin of general paralysis was the fact that many clinicians had seen and reported cases of general paralysis in which syphilis had not previously occurred and that numerous cases were now known in which syphilis was contracted after the onset of the symptoms of general paralysis The argument used to support the doctrine, "No syphilis, no general paralysis," based upon statistics showing a high percentage of antecedent syphilis in cases of general paralysis, was marred by a constant failure to take into account the fact that only a very small proportion of syphilitics ever became general paralytics or tabetics. Similar statistical evidence could be adduced showing that very high percentages of persons affected by tuberculosis had previously had measles Indeed, they knew that an attack of measles predisposed to tuberculosis, yet they did not on that ground conclude, "No measles, no tuberculosis" Moreover, the syphilitic hypothesis did not explain the clearly established fact that there were other conditions, such as chronic alcoholism, lead poisoning, and excessive meat diet, which favoured the development of general paralysis. Post mortem examination of the non nervous organs or tissues of the body in cases of general paralysis showed that an active bacterial toxæmia was present Dr. Lewis Bruce and Dr Robertson had directed attention to the gastro intestinal disorders that occurred in cases of general paralysis and had published their belief[1] that general paralysis was dependent upon a toxæmia of gastro-intestinal and bacterial origin, but Dr Bruce had since modified his view so as to regard toxic infection by the bacillus coli as a secondary or terminal infection and not as a primary cause of general paralysis More recently the hypothesis had been advanced by Dr. G D. MacRae, Dr John Jeffrey, and Dr. Robertson himself that general paralysis was the result of a chronic toxæmia dependent upon the excessive development of bacteria not only in the alimentary canal but in the nasal tract and throat, and especially upon the abundant growth of a diphtheroid bacillus which gave the disease its distinctive characters The recognised causes of general paralysis, such as syphilis, alcoholism, plumbism, and *excessive meat diet, acted as stimulants of the leuco*blastic tissue of the bone marrow or directly damaged this tissue, so that the defences of the body against the invasion of bacteria were diminished or damaged. The marrow cells (myelocytes) from which the polynuclear leucocytes were derived had a definite limit as regards proliferative capacity, so that after long periods of damage sustained or of excessive proliferation undergone they could no longer generate leucocytes for the defence of the body against bacteria. The protective functions of the body were thus impaired and in such circumstances the bacteria of the alimentary canal, nose, and throat normally present as saprophytes assumed a pathogenic character by reason of the protective forces of the body being weakened Hence arose a condition of bacterial infection and invasion from the alimentary canal and upper respiratory tract. In such conditions the body, if it desired to survive the invasion of such toxins and bacteria, was obliged to increase its auxiliary defences —that was to say, body cells which ordinarily took only a subordinate part in the destruction of foreign invaders were now roused to active antitoxic or phagocytic functions It was only in constitutions damaged to this extent that a special toxæmic and saprophytic infection occurred which led to the development of general paralysis This special infective agent, the one which was dominant in, and was characteristic of, the onset of general paralysis—was a diphtheroid organism—i e, one resembling the Klebs Loffler *bacillus in culture and morphology,* but not identical with it, and the view was advanced that this organism was an "attenuated form" of the Klebs-Loffler bacillus It had a pathogenic action upon rats The febrile rises of temperature, the disorders of digestion, the leucocytosis, the chronic sore-throat and septic condition of the mouth observed in general paralytics, and the frequently obtainable evidence of chronic bronchitis all tended to show that the general paralytic was suffering from a bacterial toxæmia The stomach, throat, and lungs of the general paralytic usually showed evidences of chronic catarrh The stomach itself might show little or no alteration but the ileum was constantly affected The tonsils of the general paralytic were frequently enlarged or more commonly they were extremely atrophic The crypts of the tonsils were filled with pus an [illegible] ences of long-standing local [illegible] development of plasma cells [illegible] ked such areas of local bacterial infection. These plasma cells were auxiliary defences of the body and their great development in such localities was an indication that a special call had been made upon them to combat bacterial invasion. Cultures made during life from the nasal and pharyngeal secretions of general paralytics resulted in the development of micro-organisms far in excess of the normal in numbers. A washing from the stomach in one case of general paralysis showed great numbers of bacteria. The septic cystitis to which general paralytics were specially prone was attributable to bacteria absorbed from an unduly septic alimentary canal and excreted by the kidneys in the urine. Cultures were made in post-mortem examination of 20 cases of general paralysis, the nasal or intestinal contents being used for this purpose. In 17 cases out of the 20 the cultures furnished evidence, in addition to other bacteria, of the presence of the diphtheroid bacillus already alluded to, and in the three remaining cases the bacillus was found by other methods of detection. In eight out of the 20 cases this organism was present in very great numbers. A recent series of cultures from the secretions of the nose and throat of ten general paralytics at the Edinburgh Royal Asylum showed that the diphtheroid bacillus was present in nine cases. Out of 16 cases of general paralysis where cultures were made from the brain post mortem four showed the presence of the diphtheroid bacillus. The bacillus in these four cases must have obtained an entry either by the blood or by local infection of neighbouring parts (internal nasal cavities or internal ear). A filamentous variety of the diphtheroid bacillus had also been met with in the lymphatics of the intestines in a few cases and was to be regarded as a terminal infection. The diphtheroid bacillus when introduced into the alimentary canal of rats gave rise to certain morbid symptoms which progressed until death occurred. Changes closely resembling those that were present in general paralysis were met with in the brains of these rats. The changes were observed in the nerve cells and in the non-nervous tissues (blood-vessels and neuroglia) alike. The whole body of facts included in the above investigations therefore supported the view of the specific bacillary origin of general paralysis of the insane.

---

[1] Brit Med. Jour, June 29th, 1901

In the discussion which followed the PRESIDENT stated his belief that in the vast majority of cases and upon the weight of indisputable evidence syphilis was an antecedent of general paralysis The results of trophic peripheral changes led to secondary catarrhs and bacterial infections (tonsillary, bronchial, intestinal, and a variety of others) in various parts of the body, but these he regarded as natural to the later stages of general paralysis and as non-essential to its causation.

Professor D. J. HAMILTON (Glasgow) mentioned a rare case of bacillary infection of the spinal cord which followed upon a railway accident without external injury in a young girl.

Professor J. G. ADAMI (Montreal) cited evidence to show that bacteria of low virulence and their toxins might have undoubtedly a progressive action upon the nervous system. General paralysis was a chronic state leading steadily to a greater and greater weakness of the body as a whole, favouring what he had termed "sub-infections" of various types, and while prepared to believe that a diphtheroid bacillus might be an accessory factor in general paralysis he would be cautious in accepting it as a specific agent in the production of the disease.

Dr. J. F FLASHMAN (Balmain, Australia) thought the facts brought forward might be of assistance in explaining cases of general paralysis not due to syphilis.

Dr. FLETCHER BEACH (London) inquired whether the bacillus and the lesions attributed to it had been met with in cases of juvenile general paralysis the etiology of which was almost invariably syphilitic.

Dr. F. W. MOTT (London) said he still believed that syphilis was the most important and frequent cause of general paralysis. He inquired whether the diphtheroid bacillus was met with in the very earliest stages of general paralysis. He cited cases of chronic poisoning with abrin and ricin in animals where changes in the brain were produced resembling in many respects those of general paralysis. He also inquired whether plasma cells were present around the cerebral blood-vessels of rats fed on the diphtheroid bacillus.

Dr. W. LLOYD ANDRIEZEN (London) emphasised the etiological and clinical frequency of syphilis and described the changes in the cerebral vessels and meninges in early cerebral syphilis within three years of infection. All stages could be found between these cases and those of general paralysis supervening from 10 to 15 years after infection. There was continuity of symptoms and of pathological lesions between these two classes of affections. He also cited cases of improvement by the "intensive" mercurial treatment of general paralysis. He regarded the diphtheroid infection, like the cystitis of general paralysis, as a subterminal and secondary state not essential to the etiology of the disease.

Dr. MAULE SMITH (Wakefield) had met with a diphtheroid organism in two patients dying from asylum dysentery, but he had not found this organism in general paralysis. He inquired whether this organism was to be regarded as infective from one patient to another.

Dr. DAVID YELLOWLEES (Glasgow) was not disposed to accept Dr. Robertson's views as to the diphthero-bacillary origin of general paralysis in the face of clinical evidence which was overwhelming. He agreed that syphilis was a very frequent but not the sole cause of general paralysis.

Dr. F. EDRIDGE-GREEN (London) believed that syphilis was the cause of general paralysis and of tabes. The patient' had in many cases seemed to suffer very little from the immediate effects of syphilis and had led a very steady life afterwards, but nevertheless in 10 or 15 years' time general paralysis or tabes was developed.

Dr. J. HADDON (Denholm) was glad to think that lunacy might be due to a microbe and regarded Dr. Robertson's diphtheroid microbe as a discovery in this direction. He, however, was of opinion that lunacy (including general paralysis) was caused by civilised habits of injudicious feeding and errors of diet and thought that attention to this source might serve to prevent cases of insanity arising from gastro-intestinal disorders and consequent auto-intoxication.

Dr. E. GOODALL (Carmarthen) inquired whether the diphtheroid organism was present in the colon and at the ileo-cæcal valve, where the inhibitory action of the intestinal wall on bacteria was least marked, and whether the brains of rats fed with cultures of the bacillus showed degeneration of the tangential fibres.

Dr. T. B. HYSLOP (London) said that the accumulated work of clinicians all over the world had established syphilis as being the chief cause of general paralysis and he believed that the bacillus of Dr. Robertson was part of a terminal infection occurring in the advanced stages of general paralysis.

Dr. ROBERTSON, in reply, stated that he realised the etiological importance of syphilis, but asserted that the general and local impairment of the alimentary and respiratory tracts, permitting bacterial invasion and toxæmia, constituted the main and the essential constituents in the production of general paralysis.

Dr. R. S. ROWS (Whittingham) read a brief paper on

Cavities in the Spinal Cord,

illustrated with lantern slides. Three different cases were described and illustrated. In the first of these the cavity formation was due to atrophy of the nervous tissue and the neuroglia, in the second to syringomyelia, and in the third to hæmorrhage into the perivascular spaces and substance of the spinal cord.

THURSDAY, JULY 30TH.

Dr. HYSLOP opened a discussion on

Alcohol in its Relation to Mental Diseases.

He considered alcohol in its relationship to physical and mental processes and argued that the rôle of alcohol in the healthy human body was more evil than good and that its use was abuse. In the unhealthy body the use of alcohol was compared to a loan raised at heavy interest which might be employed to cope with immediate and pressing needs but which constituted a heavy burden on the borrower until repayment was completed. Alcohol produced an illusory sense of well-being and of mental energy and capacity without in any way enhancing mental power. On the contrary, even in moderate doses it tended to lower the ability of performing the more complex and difficult parts of any task, physical or mental. It tended to accelerate and to confuse thoughts and ideas without regard to the logic of circumstances and it stimulated the subject to restlessness and to overaction. The vascular system responded to the presence of alcohol by vaso-dilatation and by increased exudation of lymph into the perivascular tissues, and in chronic alcoholism a number of characteristic vascular and peri- vascular changes were thus set up in the brain. The increased exudation of lymph from the blood-vessels carried with it an increase in the number of extravasated leucocytes which thereafter underwent rapid destruction and dissolution. Alcohol, moreover, acted deleteriously by absorbing [illegible] the plasma, for the [illegible] he normal processes [illegible] yslop then referred to the neuron theory and to the pathological changes met with in the brain in cases of chronic alcoholic insanity as described by Andriezen, Berkley of Baltimore, and others, and stated that the lesions described by these authors undoubtedly afforded a physical and neurological basis for the clinical symptoms observed in such cases during life—viz., the amnesia, the muscular weakness, and the slowness of reaction time of the chronic alcoholic subject. In conclusion, it was suggested that alcohol *per se* did not cause general paralysis of the insane.

Dr. G. ARCHDALL REID followed with a paper on

Human Evolution with Especial Reference to Alcohol.

[illegible] at all the races of mankind [illegible] mon stock and that by [illegible] ge from the original stock [illegible], it was argued that human individuals differed in their power of resisting diseases and that the offspring tended to inherit this parental power or weakness in particular. An example of this was cited in the case of the negroes who as a race were more resistant to malaria than the British, while it was said that *per contra* the British were more resistant than the negroes to pulmonary tuberculosis. "The British, who for thousands of years have been afflicted by phthisis, measles, and whooping-cough, are much more resistant to these diseases than the inhabitants of the Western hemisphere, who have known them only during the last few generations and who are now being exterminated by those diseases." Parental disease, continued Dr. Reid, did not affect in any way, either for good or evil, offspring born subsequently; at any rate, such offspring did not inherit the disease or the good or evil sequelæ of the disease. He challenged anyone to produce genuine instances of so-called "degeneration" of the offspring arising from, or caused by, plumbism, gout, pulmonary tuberculosis, syphilis, or other diseases of the parents. The prevalent belief largely held by the profession that such diseases were actual and potent causes of "filial degeneration" he regarded as an ancient superstition resting on bad observation. The most convincing argument against the popular view was as follows. If parental disease affected the offspring subsequently born then the morbid condition thus reproduced in the offspring would be a congenital one and such congenital morbid conditions would, according to biological law, be transmitted to the descendants of the said offspring. "Under such conditions," continued Dr. Reid, "a race afflicted by any disease would undergo rapid degeneration and ultimate extinction. We know that this is not the case." People differed in their susceptibility to the "charms" of alcohol; those who craved most strongly for alcohol were those whom alcohol affected most intensely and pleasurably. Moderate drinkers, on the other hand, did not have this craving. People drank, as a rule, in proportion to their desires. The greater the internal craving the greater was the temptation to excessive indulgence and the greater would be the mortality of such persons. Published statistics on parental alcoholism and on its effect on the offspring were untrustworthy because the various sources of error were not taken into account, and most observers were, continued Dr. Reid, prejudiced in favour of a preconceived theory. If the offspring of alcoholic parents were affected by degeneration then races or families which had long abused alcohol should be degenerating and tending towards extinction. The Jews, Greeks, Italians, Spaniards, Portuguese, and South Frenchmen, who as races had long been addicted to alcohol, should then *ex hypothesi* teem with degenerate and effete individuals the result of ancestral alcoholism. Yet the evidence was very clear that these races did not teem with such products and that they were at present the most temperate (and *ipso facto* non-degenerate) people on earth. Drunkenness in the ancestry was the cause of temperance among the descendants; hence the progeny of drunken parents tended, after the lapse of generations, to become temperate men and women with no craving for alcohol. Dr. Reid then briefly touched upon the use of opium in Eastern countries and concluded by enunciating the proposition that repressive legislation against alcoholism was useless among civilised nations. It had been tried on hundreds of occasions during thousands of years and had universally failed except among the Mahomedans and with them success was only partial.

Dr. CHARLES A. MERCIER (London) referred to the enormous value of alcohol as a stimulant in states of exhaustion and as a hypnotic in many cases of insomnia. He did not believe in the possibility of correlating specific changes in the structure of the brain tissue with changes in consciousness, for how could the structural change, he argued, help us to understand why the patient in whose brain they occurred suffered from a delusion of persecution or a mnemonic delusion? No research into structural change would ever explain such phenomena. Dr. Mercier then proceeded to criticise at some length several of the propositions laid down by Dr. Reid. As regards the inheritance of acquired characters which Dr. Reid opposed he (Dr. Mercier) could, like all physicians experienced in mental disease, adduce numerous instances showing that alcoholism of the parents affected the offspring deleteriously, but he was aware that Dr. Reid evaded the consequence of such facts by stating that the morbid conditions seen in the offspring were not the result of alcoholism in the parents but were the outcome of other causes.

Dr. YELLOWLEES said that the effects of alcoholic indulgence varied especially with the temperament of the drinker. Some men never suffered from delirium tremens however long or deeply they drank, others became insane [illegible] ally [illegible] onic [illegible] not manifest even these but sank gradually into chronic alcoholic dementia. He had noticed climacteric melancholia as a result of drinking habits indulged in early life—a heavy penalty paid for the errors of youth.

Dr. T. N. KELYNACK (London) referred to the importance of recognising the occurrence of auto-intoxication and to the remote and indirect "*secondary infections*" predisposed to by alcoholism. He thought that the morbid psychology of alcoholism would be a fit subject for collective investigation.

Dr. EDRIDGE-GREEN said that in discussing the transmission of acquired characters a distinction should be drawn between those characters which were acquired through the desire of the individual and those which were accidental, like the loss of an arm.

Dr. A. T. SCHOFIELD (London) thought that Dr. Reid had revived an old fatalistic theory which was believed to be dead. Tendencies to disease were inherited, but some tendencies of this nature might be resisted and overcome by hygiene and to this category belonged some of the evil tendencies transmitted to the offspring of alcoholic parents.

Dr. J. J. RIDGE (London) said that several of the links in a chain of argument might be correct though the conclusion might be absurd. Already life assurance societies were awakening to the fact that alcoholic indulgence, even in moderation, produced degeneration of tissues in the individual which showed itself at or about the age of 60 years.

Dr. FLASHMAN thought that the view held by some biologists that the germ plasma was uninfluenced by the environment could not be sustained on medical grounds. Changes in the nutrition of the body affected the blood plasma and the germ plasma. Dr. Reid neglected to take into account the many counteracting influences at work which mitigated the bad hereditary effects of parental disease, including parental alcoholism. He could not agree with Dr. Hyslop's statement that alcohol restored the nerve energy temporarily and he regarded the theory of amœboidism of the neurons as discredited.

Dr. FORD ROBERTSON said that he would go farther than Dr. Hyslop in attributing importance to the effects of alcohol in damaging the defensive forces of the body generally and locally and in thus opening up avenues for the invasion of bacteria. He regarded Dr. Reid's 16 propositions as bristling with fallacies. On general physiological grounds they were justified in regarding the germ cells as affected by nutritional conditions as other cells were. The onus of proof that the cells were unaffected by nutritional disturbances (alcohol and other toxic agents diffused in the blood plasma) lay with Dr. Reid. He awaited with confidence the further accumulation of evidence on this point, as he was convinced that alcohol affected the germ and sperm cells and was a potent factor tending towards the degeneration and death of the offspring thus affected.

Dr. ANDRIEZEN (London) said that alcohol acted on the tired brain as a spur on a jaded horse. It did more damage to the nervous centres than simple fatigue would cause. It also deprived the tissue of the oxygen necessary for its metabolism. He had ample and indisputable evidence to prove that the "thorns" and "gemmules" of the cortical nerve cells, both human and animal, were normal structures. He referred to researches published by him in 1894 on alcoholic insanity in which a correlation was shown to exist between cerebral changes in the nerve cells and fibrils on the one hand and such clinical symptoms as muscular weakness and tremor, amnesia, and slowness of reaction time on the other. He believed that Dr. Reid's views were founded on a misconception of Weismann's theory of the so-called "isolation" of the germ plasma and adduced evidence from cases of idiocy and imbecility and from the investigation of the "Jukes" family showing that deep and far-reaching degeneration of descendants resulted from the alcoholism of parents.

Dr. **Heywood Smith** (London) had observed a characteristic symptom in female inebriates—viz., lying—and inquired whether it was common in cases of alcoholic insanity.

Dr. **Fletcher Beach** referred to a conjoint inquiry carried out by him with Dr. G. E. Shuttleworth a few years ago, as the result of which he concluded that idiocy and imbecility were common and frequent in the offspring of alcoholic parents. A man or woman who had "soaked" freely in alcohol for years could not be regarded as having sound and healthy germ cells or sperm cells. He believed that public opinion should be enlightened before repressive legislation was proposed, and when the morals of the nation were elevated there would be little need for such legislation.

Dr. **Wilfred J. Harris** (London) said that alcohol was not a strength-sustaining agent and was discarded by men training for swimming long distances or other feats of prolonged neuro-muscular work.

Mr. **James Stewart** (Clifton) stated that in his experience nearly 40 per cent. of neurotic patients who had been under his care during recent years owed their disease to parental alcoholism.

The **President**, in summarising the subjects discussed, pointed out that the marked amnesia of chronic alcoholism, as well as the marked retardation of reaction time, were due to fine cerebral lesions affecting the cortical neurons. He could not accept Dr. Reid's view that alcohol did not prejudicially affect the germ plasma. As regards the right use of alcohol he felt that under the control of the reasoning and moral faculties the use of alcohol was in certain conditions advantageous.

Dr. **Hyslop** and Dr. **Reid** then briefly replied to the criticisms and comments made on their respective papers.

Dr. **Alice N. V. Johnson** and Dr. **Goodall** communicated a joint paper on

The Action of the Blood Serum from Cases of Mental Disease upon the Bacillus Coli Communis.

Starting from the view, now generally accepted, that excessive growth of intestinal bacteria might occur when the inhibitory action of the intestinal wall on bacteria was diminished, it was argued that excessive growth of the bacillus coli communis might especially be looked for in states of reduced health commonly associated with the progress of mental disease. Blood from 25 cases of insanity of various kinds was taken. Of these 11 were cases of acute mania, five were cases of melancholia, two of delusional insanity, one each of puerperal insanity, climacteric insanity, recurrent mania, and alcoholic insanity, and three were cases of general paralysis of the insane. Blood serum was prepared from each case and its action was tested upon cultures from mixed strains of the bacillus coli communis in order to ascertain whether, by the demonstration of agglutination, direct evidence could be adduced of the morbific influence of the said bacillus in such cases, or whether indirect evidence of the like nature could be obtained of the influence of other organisms related to the bacillus coli communis. The results of these experiments, which were cited in detail by Dr. Johnson, showed that agglutination was present in 60 per cent. of all the cases, such agglutination being good in 28 per cent. and only partial in 32 per cent. of the cases. Enumeration of the leucocytes was also practised in 13 cases of various forms of insanity, the blood being investigated once a week for a period of 14 weeks. The highest number of leucocytes was found in cases of acute mania, and in these and all other cases the leucocytes were found in largest numbers when the patients were passing through acute states of insanity, the numbers falling to half or less during states of remission or of recovery. These experiments and observations tended to show that bacteria played an important part as toxic agents in the acute stages of some varieties of insanity and that leucocytosis was a valuable indication of states of exacerbation, of recovery, or of remission.

PATHOLOGY.

Friday, July 31st.

Mr. **K. W. Goadby** (London) opened the proceedings with a demonstration and a short paper on

The Use of a System for keeping Records of Bacteriological Investigations.

He employed cards of two kinds: small ones for recording each investigation made and which formed a kind of journal and large ones on which the information gained from these was tabulated. This arrangement, as well as the tabular form printed on the cards, was the outcome of many trials. The cards were kept filed in drawers, were compact, easy for reference at any time, and cross references and comparisons were easily made. Guide cards of a different colour, blank, but with a projecting piece for a name, served to indicate groups of cards.

The **President**, Professor **D. J. Hamilton** (Aberdeen), made some remarks in praise of the system and then as Dr. **I. Walker Hall** (Manchester) was unavoidably absent his communication on

The Purin Bodies of Human Fæces in Health and Disease

was read by one of the secretaries of the section. Observations by various people had established the fact that nuclein was known to be excreted by the bowel. Only very slight traces of free purin bodies had been found and uric acid never. To determine the amount of fæcal purin excreted by different individuals under varying conditions necessitated the maintenance of a fixed diet. The fæces were taken in periods of six days. By the process employed the total purin bodies were finally obtained as silver compounds. An aliquot portion was taken for estimation of the total purins and the remainder was subjected to a special process for the separation of the individual purin bases. Up to the present 40 studies had been made upon three individuals. They showed that upon the same diet, even at intervals of three and six months, the same individual excreted daily practically equal quantities of purin bodies in the fæces. These amounts were least upon a milk diet—i.e., purin-free food—and most upon a vegetable diet. The intermediary position was held by the mixed diet. When large doses of pure hypoxanthin and xanthin were added to the food the fæcal purins were not increased. The administration of 0 5 gramme of guanin led in one subject to a marked increase—about 60 per cent. reappearing in the fæces. In another person guanin was better absorbed but still a large amount was excreted in the fæces. 500 grammes of pancreas gland caused an increased excretion of purin and only about 60 or 70 per cent of the total quantity was absorbed. The quantitative separation of the fæcal purins showed that guanin, adenin, xanthin, and hypoxanthin were always present. About one-half of the total quantity was represented by guanin, one-quarter by adenin, and about an eighth each by xanthin and hypoxanthin. It was probable that any guanin which occurred in a free state in the alimentary tract was oxidised to xanthin. In ordinary circumstances it was improbable that any of the food purins were voided by the fæces. When the dietary contained large amounts of nucleins, as, for instance, in sweetbread, it was possible that only a certain proportion was decomposed or absorbed and the remainder would appear in the fæces. The figures obtained suggested that there was a distinctly personal factor in the absorption of nuclein and its derivatives. There was little doubt that in experiments upon general metabolism the fæcal purins should always be estimated, although from a clinical standpoint their slight variations might be neglected. An attempt to isolate nuclein from the fæces in a sufficiently pure condition for elementary analysis had so far not yielded successful results because of the difficulty of an entire removal of the mucin. The presence of guanin, adenin, xanthin, and hypoxanthin in the fæcal nuclein suggested an origin from the cell nuclei of the intestinal mucous membrane, but it was possible that the pancreatic juice might contain some free guanin. In diarrhœa and inflammatory conditions of the mucous membrane the purin bodies were increased. In a case of subacute rheumatism they had been unaltered in the acute attack, a subacute attack, and during convalescence six months later. In the normal adult the fæcal purin yielded daily about from 0·01 to 0·023 gramme of nitrogen (from 0·025 to 0·0575 gramme of xanthins), a very small amount in comparison with the 0·16 gramme of nitrogen (0 58 gramme of uric acid and xanthins) passed in the urine on a purin-free diet. It was known that a small quantity of nucleo-albumin might be met with in the urine and that it arose from shed epithelium; similarly a certain amount of nucleo-albumin must be daily shed by the bronchial, pharyngeal, and nasal membranes. The remaining tissue cells passed their decomposed nuclein into circulating fluids of the body. It was obvious that in all inflammations the excretion of purin would be increased. Dr. Hall thought that these facts indicated the general absorptive and selective faculty of the intestinal epithelium of an individual whose factor had been attained and would assist in the determination of dietaries and therapeutic measures.

Professor **SENATOR** (Berlin) spoke a few words on the subject and then one of the secretaries read a paper on

A New Method for the Determination of Uric Acid in Urine,

by Dr. A. F. **DIMMOCK** (Harrogate) and Mr. F. W. **BRANSON**, F.I.C., F.C.S. (Leeds). They had devised the following method which had been found to work easily. 100 cubic centimetres of the urine were taken and warmed to about 40° C. and then saturated with 31 grammes of chloride of ammonium, [illegible] ered measuring glass [illegible] complete solution of [illegible] The contents would then be at a temperature of about 15° C. and should be left for at least two hours (preferably 12) for the precipitate of urate of ammonium to subside. Should any of the precipitate have a tendency to remain near the surface a gentle rotation of the measuring glass would cause it to settle. The supernatant liquid was poured off and the portion left was to be carefully filtered through a small filter paper (diameter about 5·5 centimetres), as by Hopkins's method. The precipitate was carefully washed with a very dilute solution of ammonia, consisting of 1 part of strong solution of ammonia in 1000 parts of distilled water. The precipitate was best washed in the following manner. The liquid was allowed to drain from the precipitate and the filter paper was then filled with the dilute ammonia solution contained in a wash bottle. This was allowed to drain off and the filter paper was again filled with the ammonia solution. This operation was to be repeated a third time. Some of the filtrate was tested with a 5 per cent. solution of nitrate of silver acidulated with nitric acid 5 per cent. Only a very slight precipitate should be given, indicating the absence of any appreciable amount of chloride of ammonium, but if the filtrate still contained this salt it should be washed with a small additional amount of dilute ammonia. The precipitate with the filter paper was placed in the generating bottle of a special nitrometer, the tube being filled up to the mark (25 cubic centimetres) with the hypobromite solution and lowered into the bottle by a piece of string. The temperature of the hypobromite solution was noted; it should approximate to that of the room in which the estimation was to be made. The cork was now placed in the generating bottle and the bottle was plunged in a vessel of water of a temperature similar to that of the hypobromite solution. After two minutes the water level in the measuring burette was adjusted to zero and the apparatus was tested to see that there was no leakage. Finally, the generating bottle was tilted to allow the reagent to flow out of the tube and reaction between the hypobromite of sodium and urate of ammonium was promoted by shaking. After ten minutes the water levels were adjusted to equilibrium and the percentage of uric acid was read off as indicated by the nitrogen evolved. The burette used was graduated specially from the results of numerous determinations and the method seemed to be quite suitable for proportions of uric acid ranging from 1 in 1000 to 1 in 10,000. By the addition of a second scale to the burette the instrument could be used as a ureometer.

Dr. G. L. **EASTES** (London) remarked that the method appeared to be very satisfactory (if the graduations on the burette were to be relied on) in that it shortened the time taken in estimating uric acid by Hopkins's method by from four to six hours.

Dr. F. G. **BUSHNELL** (Plymouth) read the last paper on

The Differential Leucocyte Count and Estimation of the Leucocytes in 41 Cases,

including 20 cases of malignant disease, three of leukæmia, two of Hodgkin's disease, two of beri-beri, one of blackwater fever, one of malaria, one of (?) Addison's disease, and one of hypertrophic cirrhosis of the liver. Besides the paper giving Dr. Bushnell's remarks on the cases a table was added containing details of the blood counts.

Dr. E. R. **CARLING** (London), in the course of some remarks on this paper, stated in regard to a series of cases of appendicitis in which he had counted the leucocytes that in those cases where the leucocyte count had amounted to 20,000 per cubic millimetre pus was found at some time or other either before or after, but that pus was not found in any of those cases in which the leucocytes were less than 20,000 per cubic millimetre.

After some concluding words by the **PRESIDENT** of the section the meeting came to an end.

In addition to the papers, discussions, and lantern demonstration the section provided a pathological museum containing more than 120 macroscopic pathological specimens, many of them of very great interest, which were lent from various institutions or by private individuals, besides a valuable series of radiograms, photographs, and drawings of pathological conditions and about 30 microscopic specimens. Dr. D. E. Evans (Swansea) and Dr. Newman Neild (Bristol) were responsible for the excellent arrangement of the museum.

OPHTHALMOLOGY.

FRIDAY, JULY 31ST.

Mr. **GUSTAVUS HARTRIDGE** (London) opened a discussion on

The Treatment of Convergent Squint.

He said that the treatment of concomitant convergent strabismus in a scientific manner could only be approached by the consideration of the various factors which helped to produce the disorder and by a careful examination of every case so that the value and importance of each factor might be ascertained It was known to all that concomitant convergent strabismus was a condition affecting both eyes, a binocular defect, and the result of excessive innervation of the internal recti muscles excited by the associated act of accommodation. The factors which assisted in the production of squint were: (1) hypermetropia; (2) imperfect development of the fusion faculty; (3) defective visual acuity in one eye; and (4) the anatomical position of rest of the eyes. These various factors did not play the same part in every case; they might not all be present, hence a careful and systematic examination of each case was essential. The objects to be obtained by treatment were: (1) the correction of the deformity; and (2) establishment of binocular vision for all distances He divided the treatment into three classes: optical, orthoptic, and operative. The importance of an exact optical correction was beyond all question and in many cases resulted in a complete cure. Orthoptic exercises were of great value in many cases but must be commenced early. They consisted of: (1) covering up the fixing eye for a certain time daily; (2) practice with a stereoscope or one of the special instruments devised for [illegible] out for 12 months before any operative treatment could be entertained. When an operation had been decided upon they had to decide what operation should be undertaken. They had at their disposal four operations: (1) simple tenotomy of one or both eyes; (2) simple advancement; (3) tenotomy with advance of the opponent muscle; and (4) stretching of one of the muscles. The chief points on which he invited discussion were: (1) when was an operation necessary or justifiable? and (2) what operation gave the best results? In his view the conjunction of tenotomy of one muscle with advancement of the other gave the best results; he was distinctly adverse to operating on both eyes at the same sitting. As to the age for operation, that must be determined by the condition of the field of vision in the divergent eye. They had always to bear in mind the deformities produced by operation, sunken caruncle, limitation of movement, alteration of width of palpebral fissure, and the like; each case had to be considered in view of these after-effects. They had also to bear in mind that squints the increase according to the statements of competent veterinary surgeons. As a rule infection probably occurred from bovine tubercle bacilli passing through the intestinal wall. Then the mesenteric glands became affected and afterwards the retroperitoneal glands. When these cases were examined bacteriologically it would be found that although the actual bacillus appeared to be the same as that which was present in the pulmonary tubercle of adults, yet the culture growth was quite different. The growth corresponded exactly with that from bovine tubercle and was entirely distinct from that which was derived from human tubercle. With regard to the tuberculosis of cervical glands in children, again he thought that they depended upon an infection with bovine tubercle through the tonsils and the naso-pharynx. It would appear likely that the bovine tubercle bacillus was very virulent so far as young subjects were concerned, but that it had but little action upon adults and that the tubercle bacillus of the adult human being was not so virulent to children. Further, it might be that an infection with the bovine organism protected from future infection with the human bacterium. In cases of tuberculous meningitis he was sure that there might be the meningeal condition without any other signs of tubercle and he considered that there might have been direct infection of the meninges through bacilli having gained entrance from the pharynx into the blood stream.

The PRESIDENT (Mr. W. ARBUTHNOT LANE, London) congratulated Dr. Raw on the clear manner in which he had stated his conclusions. He thought that in many cases of tubercle in children, including tuberculous meningitis, there had been a previous traumatism, for it was rare for the bacillus to infect wholly healthy organs. Glands in the neck might first have been infected with some other bacterium and then with the tubercle bacillus. In abdominal tuberculosis again there was usually a previous history of intestinal disturbance.

Dr. D. A. REID (Tenby) considered that it was the duty of every medical man to render all the aid in his power to the elucidation of the question of infection. He drew attention to the fact that the natives of India and even their children were peculiarly free from tubercle, while European residents there and their offspring were very liable to the disease and he believed that this was due to the fact that the native eschewed beef and cow's milk and only partook of goat's milk, the goat, perhaps, being the animal least likely to be attacked with tubercle.

Mr. JOHN MACKENZIE (Kirkby-in-Ashfield) had seen one case of tuberculous disease of the nipple in a woman, but she did not give her offspring tubercle. He considered that most cases of tuberculous meningitis were preceded by disease of the middle ear.

Dr. THEODORE FISHER (Bristol) thought that the reason why children suffered so much more than adults from tuberculous glands in the neck was not that they were more susceptible to bovine tubercle but because all adenoid tissue in the young was very prone to be inflamed. Again, he believed that abdominal tubercle might arise from a bronchial infection, for the secretions, in the tubes might swarm with tubercle bacilli. He did not believe in the ascending spread from the abdominal to the thoracic cavity.

Mr. C. G. HIGGINSON (Birmingham) stated that experiments on human subjects with bovine virus were constantly being made, for much milk drunk was tuberculous. Dr. Raw had again put the profession on its guard against milk and, he considered, rightly so.

Dr. W. L. SYMES (Dublin) did not like the term "tabes mesenterica." He considered that there were three varieties of abdominal tuberculosis: one in which the peritoneum alone was involved; the second in which only the mucous membrane of the bowel was diseased; and the third—a rare form—in which the mesenteric glands alone were affected. This last was the only one that deserved the term of "tabes."

Dr. E. CAUTLEY (London) admitted that he believed that bovine tuberculosis might occur in children, but he was sure that it was very rare and that infection with human virus was much more common. He considered that the expression "tabes mesenterica" should be dropped at once. He believed that tubercle in cattle was not so frequent as was thought. He considered that the bulk of it was found in pedigree cattle and those kept in towns. He was sure that the bronchial glands were even more frequently infected than the abdominal glands. Acute tuberculosis was rare in children except when it occurred in the lungs. He thought that condensed milk as an article of diet tended to make children susceptible to tubercle.

Dr. CARPENTER (London) said that he had seen cases of so-called "tabes mesenterica" in children who had been fed entirely upon breast milk.

Mr. W. MCADAM ECCLES (London) expressed his conviction that a large number of cases of tubercle in children were the outcome of a primary infection with another organism which paved the way for the tubercle bacillus. This was particularly so in the case of the cervical glands.

Dr. RAW, in his reply, referred to the very complex nature of the subject and reaffirmed his conviction that there were many cases in which the tuberculous infection spread from the abdomen to the thorax. With regard to Swiss condensed milk, it must be remembered that until lately this in itself was a source of infection in all probability, containing as it did some years ago many tubercle bacilli of the bovine form.

Adenoid Vegetations in Infancy.

Mr. R. C. DUN (Liverpool) wished to draw attention to the possible existence of adenoids during the first year of life. Some instances would appear to be truly congenital, symptoms referable to the condition being present at birth. He believed that a considerable number of infants suffered from a slight degree of adenoid vegetations, as evidenced by mild symptoms of nasal obstruction and catarrh. But there were also not a few cases in which more severe and even grave symptoms might be present. These would materially interfere with the health of the infant and did not tend to improve with ordinary medical treatment. There were several forms of the affection: the first in which there were marked nasal obstruction and catarrh, with or without epistaxis; the second in which reflex nervous phenomena were the principal manifestations of the trouble, without any real nasal obstruction (such signs might be convulsions, laryngeal stridor, and vomiting); the third those in which secondary septic affections predominated, these being chiefly septic adenitis and otitis media; and, lastly, those cases in which nasal obstruction was present and was associated with nervous and septic conditions. In by far the larger number of cases of adenoids in infancy the symptoms were slight and did not call for active operative treatment, but, on the other hand, there were certainly some cases, comparatively few in number, in which the signs and symptoms were such as to demand removal of the adenoid growth. In these the improvement that followed operation tended to confirm the fact that the various phenomena that the infant presented were in reality due to the lesion in the naso-pharynx.

LARYNGOLOGY AND OTOLOGY.

WEDNESDAY, JULY 29TH.

Sir FELIX SEMON (London), in introducing the discussion on

The Operative Treatment for Malignant Disease of the Larynx,

gave a historical retrospect, first referring to the period of therapeutic nihilism, then to Czerny's experiments and to the first operations. The mortality attending the first thyrotomies led to destructive criticism, and Paul Bruns in 1879 condemned the operation. The diagnosis in those days was imperfect and so was the technique. Butlin reinstated thyrotomy in 1889 and with better means of early diagnosis and improved technique of the operation good results followed, so that in the present day if a case remained cured after one year had elapsed since the date of the operation the patient was in the same position, so far as the disease was concerned, as if he had never had malignant disease of the larynx. Sir Felix Semon reminded his listeners of the dangers of statistics. Collected statistics from various observers and various operators at different periods gave rise to erroneous conclusions. The statistics of individual observers were alone trustworthy. He said at the present time that there were five different operations at their disposal. 1. The intralaryngeal method. Its field of usefulness was extremely limited. It was conceivable that when the disease was limited to the epiglottis it might be removed by this method, but the endolaryngeal operation had its drawbacks and was generally unsuitable in malignant disease. 2. Thyrotomy, with or without the removal of smaller fragments of cartilages. This, in the speaker's opinion and experience, was in suitable cases a perfectly ideal operation.

3. Partial extirpation of the larynx. 4. Total extirpation of the larynx. The recent improvements in its technique had increased the legitimacy of this operation in desperate cases. 5. Subhyoid pharyngotomy was of limited applicability. Speaking of the difficulties in diagnosis he said that cases of malignant disease of the larynx might be classified under three heads: Firstly, those in which everyone could make the diagnosis; secondly, those in which only experts could make the diagnosis; and thirdly, those in which no one could make the diagnosis. He advised the removal of a piece of the growth by the endolaryngeal method for a pre-microscopic examination, but when in doubt about the diagnosis their duty was to treat the case as one of malignant disease.

Dr. E. J. MOURE (Bordeaux) through illness in his family was unfortunately prevented from being present to take part in the introduction of the discussion.

Professor TH. GLUCK (Berlin) made an exhaustive communication upon the operations for malignant disease of the larynx and adjacent structures. He dealt mainly with the operations for the partial and total extirpation of the organ. After referring to the works of the pioneers in this branch of surgery he briefly described his manner of operating for the relief of stenosis and cicatrisation of the trachea and larynx, and passed to a consideration of thyrotomy and laryngotomy for diffuse papillomata and circumscribed cancer of the vocal cord as well as operations for the loss of substance caused by exfoliative necrosis of the laryngeal cartilages. In connexion with the operations he had performed for the eradication of cancer in this region he had successfully extirpated the pharynx, the larynx, the œsophagus, the entire thyroid gland, the vagus nerve, the cervical portion of the carotid and jugular vessels, and had obtained cures of two and a half years' duration. The mortality following operations for extirpation of the larynx hitherto had been due to septic broncho-pneumonia. To combat this he performed a prophylactic resection of the trachea by which a wall of tissue—a living impermeable diaphragm—was interposed between the cavity and wound of the operation and the lungs, which rendered aspiration of foreign bodies into the lungs impossible, the trachea being shut off from the pharynx and œsophagus. In hemilaryngectomy, laryngotomy, and total extirpation of the epiglottis a plastic operation, based on the same principle, was performed. After healing of the wounds the patients could partake of food like normal individuals. The duration of development of cancer of the larynx and pharynx might be even some years before the symptoms were sufficiently marked to bring the disease under notice; on the other hand, the duration owing to hæmorrhages or hoarseness might be very short. An early diagnosis and a radical operation were the essentials for recovery. Diabetes, heart disease, or advanced age did not form absolute contra-indications for operations. Amongst the complications arising from the operations for extirpation of the larynx were uncontrollable hæmorrhage from the bowels; hemiplegia, or perhaps loss of consciousness and death following ligature of the carotid artery; rise of temperature and pulse-rate which might be due to sepsis, iodoform poisoning, or heart failure; bronchitis; embolism; phlegmon of the posterior wall of the trachea and of the mediastinum; and myxœdema. Professor Gluck indicated how these possible complications might be anticipated or combated. Speaking of the results obtained from the various operations which he had performed for carcinoma of the larynx and pharynx, he said that in four cases the vocal cords had been extirpated by laryngo-fissure with excellent results, the patients remaining well for six months and two and a half, three and a half, and four years, respectively. Hemilaryngectomy had been performed in 35 cases with only three deaths, one after 24 days from sudden heart failure, another independently of the operation from a phlegmon of the right gluteal muscle, and the third from pneumonia on the fifth day. From amongst a series of 22 cases of total extirpation, there had been only one death and that on the eleventh day from iodoform poisoning in an old man, aged 70 years. Amongst the 27 transverse extirpations of the larynx and pharynx, mostly with glandular extirpation also, there had been only one death. These results compared with a previous series of cases marked brilliant progress. In a former series of nine cases—certainly very serious cases—there had been four deaths, and going back to 1888 and the first cases there had been only two recoveries out of ten operations. The operation lengthened life, renewed hope, and if after a year, or a year and a half in the more desperate cases, relapses occurred, then according to the speaker's experience the end was less painful to the patients, and in the interval the patients had lived contentedly, and in some cases merrily, till the relapse brought death rapidly. Professor Gluck said that he could have brought forward 38 of his patients, some of whom had survived the operation 11, 8, 6½, 5½, 4½, and 3½ years and in full health. Others had died from other illnesses and not from recurrence of the disease. In consequence of the length of the journey he had brought only two with him; both had been the subjects of cancer of the larynx and pharynx. In the one case five years and in the other three months had elapsed since the operation. The older case had been twice radically operated upon, with total extirpation, resection of the pharynx, the great vessels of the neck, and the vagus nerve; the patient spoke with a pharyngeal voice and followed his calling of a farmer. The second spoke with the nasal-phonetic apparatus which had been devised by Professor Gluck and which was demonstrated. Professor Gluck detailed and demonstrated by means of diagrams the various stages of the operations he had spoken of and also demonstrated a series of laryngeal and cancerous growths he had extirpated. The majority of the individuals to whom the organs and growths belonged were alive and well.

Dr. HERBERT TILLEY (London) referred to some points in the technique of the operation. For checking the oozing from the wounded parts in the larynx he had found Whitehead's varnish a most excellent antiseptic and styptic. He had observed subsequently to the operation small granulations in the anterior commissure at first suggesting a recurrence, but which were due to the stitches used in closing the cartilage.

Dr. W. JOBSON HORNE (London), speaking from a pathological as well as from a clinical experience, considered that when an error was made in diagnosis it was more commonly on the side of regarding an innocent growth as malignant than a malignant growth as innocent. An early diagnosis was of the utmost importance, but too much value might be attached to the information to be derived from a bit of the growth removed by the endolaryngeal method for microscopic examination. A negative result from such an examination was to the case what a negative result from an examination of the sputum was to a doubtful case of pulmonary tuberculosis. He thought it better not to disturb the growth by the endolaryngeal removal of a portion without first obtaining consent to a laryngo-fissure if deemed to be advisable, and in doubtful cases he considered laryngo-fissure should be resorted to.

Mr. R. H. WOODS (Dublin) was in favour of suturing the cartilages after thyrotomy; in his experience granulations within the larynx had not followed. He was opposed to the use of Whitehead's varnish; there was the danger of œdema following owing to the surface which it closed not being absolutely aseptic. The proper preparation of the patient he held to be a factor in preventing sepsis.

Dr. E. S. YONGE (Manchester) communicated the notes of two cases of epithelioma of the larynx remaining well two years after operation (thyrotomy).

Dr. J. DUNDAS GRANT (London) referred to the possibility of the fragment removed for microscopic examination containing no malignant growth, and to the frequency with which the disease was found on thyrotomy to be much more extensive than the laryngoscope had indicated. He thought that cases in which, before operation, there was a tendency to the regurgitation of fluids into the larynx were less favourable in their prognosis than those in which that did not exist, as there was every probability of the occurrence of "swallowing pneumonia."

Mr. C. P. CHILDE (Portsmouth) spoke of sudden death following the operation for cancer of the larynx in alcoholics.

The PRESIDENT (Dr. P. W. WILLIAMS, Bristol) congratulated the section upon the excellent discussion and expressed himself in accord with the views about the value of a pre-microscopic examination and statistics.

Sir FELIX SEMON and Professor GLUCK replied to the several points raised. Sir Felix Semon advised food from the first through the mouth; and preferred cocaine to any other styptic for arresting bleeding within the larynx. After thyrotomy he sutured the cartilages, taking care to pass the sutures through only the superficial part and not to enter the larynx.

THE LANCET.

LONDON: SATURDAY, AUGUST 15, 1903.

Insanity in Relation to Civilisation and Race Decay.

THE presidential address delivered in the Section of Psychological Medicine at the meeting of the British Medical Association at Swansea by Dr. ROBERT JONES, and published in THE LANCET of August 8th, p. 366, serves to call attention to some of the deeper-lying problems of insanity regarded from the sociological standpoint. The main theme of the address is the development of insanity, and especially of the less favourable and more degenerative varieties of insanity, *pari passu* with the march of civilisation. For though the past century has witnessed an unparalleled advance in the material, moral, scientific, and social progress of the nation this has not been achieved except at serious cost. "We find," says Dr. JONES, "that our advance has not been without sacrifices—losses here and retrogression there—and that civilisation itself has not been an unmixed blessing." For in the struggle which has marked our advancement the conflict has resulted not solely in the conquest of ignorance and in the higher achievements of science and of knowledge; the pathway of progress has been freely strewn with the wrecks and remnants of mental failure and physical degeneration. Of this sad fact evidence, patent to the casual eye sometimes and at other times obvious to the close observer, may be seen in many directions, and it is a fact that must give pause to those who regard with too great complacency the march of human progress. We may travel quick nowadays, but some of us have to pay heavy rates.

The law of survival of the fittest in the struggle for existence in its operation through the ages of human progress exacts its penalty in determining that the feeble, the degenerate, and the unfit shall perish. But man, rising superior to that law, elects that the feeble, the degenerate, and the unfit shall be cared for, housed, and preserved to live to old age and, it may be, to propagate their kind, and the accumulated results of such action are seen in the steady increase of the effete and the degenerate and in the increasing burdens imposed upon society for their maintenance. So far as trustworthy information is to be had it appears that insanity increases as man departs from the savage and semi-civilised states and approaches the highest grades of civilisation. "It is only when we come to higher civilisation," adds Dr. JONES, "that the higher forms of insanity are seen." Many factors have contributed towards the increase of nervous diseases and of insanity with civilisation and to the increased malignity and incurability of many of the types of insanity which now prevail in civilised communities. On the one hand there exist as etiological factors the greater mental toil and hurry of the modern strenuous life, the overtasking at school, the increased amount of irksome study for the learned professions, the more exciting nature of our amusements, the sensationalism and pruriency of the mental pabulum offered in newspapers and literature to all classes alike, the more stimulating character of our diet, and the restlessness introduced into life by increasing facilities of travel and communication. Moreover, among the lower strata of society the overcrowding and the unhygienic conditions of slum life in great cities, the free propagation of the weak and the unfit, the presence of a considerable neurotic and pauper alien strain, and the widespread existence of alcoholic intemperance act as contributory factors in the same direction. It is thus seen that great centres of civilisation practically manufacture their own unfit—viz., their paupers, lunatics, neurotics, and degenerates. Indeed, criminologists have even taught us in recent years that society is the broth or culture medium which favours the growth of one of its microbes—the criminal. London alone is responsible, says Dr. JONES, for the production of over 70 insane persons per week a number which, he thinks, is destined to increase.

In reference to types of insanity which are growing in numbers as in importance at the present day, Dr. JONES mentions dementia præcox and general paralysis. Dementia præcox, a disease rare in the early part of the last century, now attacks some of our most promising youth, and the condition is practically incurable. The increase of general paralysis of the insane is another serious factor in modern civilisation; while the difficulty or the impossibility of limiting the spread of syphilis has rendered the outlook in this direction grave. It seems to be generally agreed that a hundred years ago there were not only fewer cases of insanity but those which occurred were acute and curable. Not until Jan. 1st, 1859, was the number of lunatics officially registered in this country. At that date there were 36,762 insane persons—a proportion to the population of 1 to 536. To-day they number over 113,000—a proportion to the population of 1 in 293—and the tendency of much of the insanity which comes under treatment to-day is to end in dementia and to become incurable. Melancholia has shown in recent years a considerable rise among the educated and private classes of the insane and recovery is rarely the happy issue of melancholia, more especially in men. With the progress of civilisation, therefore, concludes Dr. JONES, not only is insanity on the increase but the occurring varieties are less curable, the physique of the town-dwelling section of the population has deteriorated, and the statistics of recovery from insanity are less favourable to-day than they were as comparatively recently as 25 years ago. No one reading Dr. JONES'S thoughtful address can fail to be struck with the evidence for a pessimistic view. But relief may be at hand nevertheless and may come from the same direction as the evil. The increased intellectual activity, which is now reproached for bringing in its wake a train of psychological ills, will become more disciplined in its working, when the mental health of the people will improve, and the blessings of the fuller life which modern education and modern invention have brought within their reach will be enjoyed with impunity.

The Histology of Muscle.

THE structure of muscle is a subject of perennial interest and although the description and diagrams of various observers are repeated with but little alteration in successive editions of their own treatises, it is remarkable that no two histologists who have investigated the subject at first hand agree in all points in their accounts with each other. The existence of a spiral fibre encircling the muscle fibre, as an explanation of the striation of voluntary muscle, was advocated by Mr. SKEY many years ago but has been altogether ignored by more recent microscopists. In the April number of the *Archiv fur Mikroskopische Anatomie* this old doctrine has received unexpected confirmation from Dr. KARL MUNCH, the assistant in the Pathological Institute of Geneva. This observer, in the course of his researches upon the precise limits between striated and unstriated muscle, on examining the smooth muscle cells of the œsophagus of the cat, noticed with surprise that the nuclei of such cells presented a more or less well-marked transversely or obliquely striated aspect. Further inquiries showed that the same appearance was visible in the nuclei of the muscle cells of the stomach, the intestines, and the bladder not only of the cat but of other mammals as of the guinea-pig, the rat, and the rabbit. Special arrangements require to be made for success in the observation. The lens must have a high magnifying power —viz., from 700 to 1000 linear. The specimen must be taken immediately after death, delay of a quarter of an hour causing all traces of the spiral disposition to be lost. The fragment to be examined should be treated with a 2 per cent. solution of acetic acid or with a 3 to 5 per cent. solution of citric acid. The focussing of the nuclei requires the greatest care, for the whole depth of the object has to undergo examination, and the different aspect presented by each nucleus, according to whether the superficial or deep surface or the internal substance is in focus, affords to some extent an explanation of its structure and of the presence of the spiral band. With such high powers the manipulation of even a skilled microscopist is taxed to the uttermost.

The appearances which Dr. MUNCH describes may be briefly summed up by saying that the nucleus, being supposed to rest on its side, an oblique striation is observable on the distal surface, the striæ, which are very faint, running from the left downwards to the right. On focussing the proximal surface, a more distinct striation is observable, the striæ, however, running at an angle to or divergently from those on the distal surface. If the internal substance of the nucleus is now focussed all manifestation of striæ is lost, so that the appearances presented coincide precisely with those which might be expected to occur were a fibre to be wound spirally round the nucleus from left to right. Occasionally and less frequently the striæ run from right to left from above downwards. As a means of fixation Dr. MUNCH recommends firstly the use of the smallest fragments of unstriated muscle possible and then that these should be immersed for five minutes in a solution of 3 to 5 per cent. of citric acid and afterwards treated with a 7·5 per cent. solution of sublimate; finally, they should be thoroughly washed and placed in iodised alcohol in the usual way. The striæ are anisotropous and are stained with hæmatoxylin, carmine, saffranin, cochineal, methyl-green, and thionine. The number of turns of the spiral fibre in each nucleus varies considerably. The smallest number which Dr. MUNCH has met with is three and a half and the largest he has counted with certainty is 15. The nuclei do not appear to possess a membrane, though their protoplasm is sharply limited and defined from the adjoining cell protoplasm. Having satisfied himself of its at least occasional existence Dr. MUNCH proceeds to ask the following three questions—whether the spiral figure is always present, whether it is the only morphological figure that exists in the nucleus, of what material it is composed, and what is its developmental history. In regard to the first point he has not been able to assure himself of the presence of the spiral figure in the striated muscle cells of mammals, birds, fishes, or arthropods (though in one instance he observed it beautifully marked in a thin frog that had outlived the winter), nor could he make it visible in the nuclei of the slender unstriated cells of gastropods or vermes. Still, he entertains no doubt that it forms a normal constituent of all active muscle cells and is neither an abnormality nor an evidence of degeneration, neither the indication of a resting state nor an antecedent or subsequent phase of cell division. In regard to the second question, he has not been able to see any other structure, not even a nucleolus, in the nuclei presenting a spiral figure, but this, however, is not surprising considering the minuteness of the object. In regard to the third question it can only be said that the spiral figure stains like chromatin and may therefore represent that constituent in the nucleus. In regard to the developmental history of the spiral figure he has no information to give.

Having thus exhausted the histology of the nucleus Dr. MUNCH next proceeded to inquire whether the transverse striation of striated muscle might not be due to the spiral arrangement of the anisotropous substance. It is impossible, he observes, to obtain a complete stereoscopic view of any object with the microscope, and we must therefore draw on the imagination to build up from the appearances presented by focussing at successive depths the form of an object which would result from the superposition of the several images; and there are many difficulties to overcome in the endeavour to effect this plastic reconstitution. In the first place, there is the difference between the comparatively thick muscle fibre and the extreme delicacy of the zone formed by the parallel spirally-running striæ; secondly, the irregularity of the parallel striation; thirdly, the errors arising from the peculiar refractive powers of a transparent cylinder, which, as Dr. MUNCH shows by diagrams, materially alters the direction of fine lines drawn parallel or at right angles to each other on its surface; and, lastly, there is the chance of confusion arising from the tendency of the fibre to split up into various sized columns, thus forming fibrils, or into discs. In the endeavour to overcome these difficulties it may be noticed that, whilst it is impossible to follow one stria completely round a fibre on account of its minuteness, however many muscular fibres are examined a true transverse striation is never met with. The striation presented by the muscular fibres is, he contends, in all animals and man, who is zealous in the practice of his profession, seeks and attains some degree of progress, and any advance which he may make as an individual should be regarded by him as an integral part of the progress aimed at by the medical profession as a whole. The writing of books by those qualified to do so with authority assists in this progress by making known the results of scientific work, by collecting and comparing results already made known, and by laying open for the general use of the profession new and improved methods in medicine and surgery. The copyright in the book or article protects only the writer's ideas in the form in which he has expressed them. It protects his work in writing the book, it neither protects nor pretends to protect discoveries in medicine and surgery; on the contrary, it is written for the express purpose of making them more widely known. We venture to question the opinion of "Patentee" that the patenting of surgical instruments in this country would benefit the profession at large by the exclusion of "cheap and nasty foreign-made instruments." The influx of these would only be increased by anything which raised the price of better articles, and even where infringements of patents were believed to have taken place the expense and difficulty of establishing patent rights would often prevent action being taken. In our view the interests of the medical profession and of the public are best promoted by the freest of free trade and the most unrestricted publicity in all that tends to aid the surgeon and the physician.

CREMATION AND CRIME IN INDIA.

OUR special correspondent in India writes: "Contrary to official expectation appreciable quantities of arsenic were easily detected in the ashes and bones from the scene of cremation. The loose regulations with regard to the disposal of the dead in India favour the crime of poisoning by arsenic very considerably, but the imperfect cremation of the body as generally practised would appear to hold out promise for the detection of the criminals." The Government of Madras, he adds, has called the attention of all district magistrates and of the inspector-general of police to the possibility of detecting arsenic in the charred remains of a cremated body. This step upon the part of the Government is a very proper one to take, since it cannot be supposed that the district magistrates could possess any specific knowledge of the subject. But we may say in regard to this question that it is well known to chemists that when organic matters are incinerated in the presence of arsenic the alkaline salts which are formed combine with the poison and fix it in the shape of non-volatile arsenite or arsenate. There is nothing very remarkable, therefore, in the discovery of arsenic in the charred remains of a body to which arsenic had been administered. The alkaline salts of the body formed on burning would be sufficient to fix the otherwise volatile arsenic and to convert it into a stable and non-volatile salt. In some classic toxicological researches, in fact, it was the custom to burn, say, a piece of liver from a case of suspected arsenic poisoning and to ignite it at a red heat. The residual ash was then searched for the presence of an arsenate.

THE DISTRIBUTION OF PLAGUE.

AS regards Cape Colony, the medical officer of health of the colony states that for the week ending July 18th the condition of the various places mentioned below was as follows. At Port Elizabeth 1 case of plague was discovered—namely, a European female on July 14th. At the Plague Hospital 1 European female and 1 coloured male died and 2 patients were discharged, leaving 3 cases under treatment. Plague-infected rats continued to be found in the town. At East London a native female was found dead from plague on July 16th. At the Plague Hospital there were no admissions, discharges, or deaths; 4 cases remained under treatment. At King William's Town no case of plague was discovered. At the Plague Hospital 3 patients were discharged and none remained under treatment. Plague-infected rats continued to be found in the town. At Queenstown 1 case of plague was discovered—namely, a native male on July 17th. At the Plague Hospital 1 case remained under treatment. Plague-infected rats continued to be found in the town. In Graaff-Reinet, Burghersdorp, Stockenstroom, or Riversdale no plague in man or animals was discovered. As regards Mauritius, the Colonial Office has received information that for the week ending August 6th there were 17 cases of plague and 14 deaths from the disease. As regards Hong-Kong a telegram from the Governor received at the Colonial Office on August 11th states that for the week ending August 8th there were 9 cases of plague and 9 deaths from the disease.

A MEDICAL PRACTITIONER AND A CORONER.

AT an inquest held recently at Southport upon the body of a labourer who had died in the infirmary from accidental injuries the coroner, Mr. S. Brighouse, addressing the jury, stated that the inquiry would have been held on the previous evening, much to the convenience of himself and, he had no doubt, much to the satisfaction of the relatives of the deceased, but for the action of the house surgeon at the infirmary. The report of the coroner's observations in the *Liverpool Daily Post* of July 31st continues as follows: "On Wednesday morning, July 29th, the Southport police, as usual, telephoned to his (Mr. Brighouse's) office at Ormskirk immediately they knew of the facts of the case. He was away, but Mr. Carr, at his office, who knew the routine of his work, at once replied that there would have to be a post-mortem examination, as Mr. Bentley (the house surgeon) had not liked to say that death was due to a fractured skull. Police-sergeant Clarke then telephoned to the infirmary requesting that a post-mortem examination should be made, but Mr. Bentley refused to do so without a written order. This result was communicated to Mr. Brighouse and he himself telephoned to Mr. Bentley and asked whether he insisted on a written order and he replied that he did. Mr. Brighouse then pointed out that this was the first occasion during his office as coroner on which a medical practitioner had refused to make a post-mortem at his request. He admitted that under the Coroners Act, 1887, the doctor was legally correct, but he pointed out that it was useful to obey his instructions. A summons was therefore served upon the house surgeon to make a *post-mortem*. He (the coroner) found that Mr. Bentley was qualified only in November last and always found that the newer a man was the more he fancied he was the whole Royal College of Physicians." Mr. Brighouse then invited the jury to censure the house surgeon and the jury seem to have fallen in with his request. Mr. Brighouse's comments will appear to all who consider the circumstances to have been entirely uncalled for, and the fact that they should have been made publicly and that a jury should have been asked to indorse and to support them will add no weight to them. The views of a judicial officer, such as a coroner, particularly if they are not consistent with good sense or with the law, gain nothing from the approval of the worthy citizens composing the jury, who in this case heard only the coroner's side and not that of the house surgeon. When Mr. Bentley refused to make a post-mortem examination upon the authority of a telephone message from a policeman who had had a telephone message from a Mr. Carr, who was not the coroner, Mr. Bentley acted wisely. If he had made a post-mortem examination and if it had afterwards turned out that there had been some mistake in the message transmitted or that Mr. Brighouse refused to confirm the decision of Mr Carr, Mr Bentley alone and not the coroner, or Mr Carr, or the *police sergeant, or the telephone company* would have had to bear the responsibility He might have been subjected to reproach or censure at the hands of the relatives of the deceased or of the coroner When Mr Brighouse was informed of the matter, and of the attitude adopted by the house surgeon, it was for him to forward the proper authority without delay rather than to press Mr Bentley to commit an informality the risk of which, however *small, would have affected Mr Bentley and no one else* In any case no man should be publicly attacked by a public official for refusing to take a risk in order to further the convenience either of the official or of other people The tone and temper of Mr Brighouse's remarks may be judged by his observations regarding Mr Bentley's youth On such occasions young men have far more need to keep themselves within the letter of the law than those of greater eminence Mr Bentley probably acted as he did not because he "fancied he was the whole Royal College of Physicians," but because he knew that as house surgeon of the Southport Infirmary he would have to answer to the managing body of that institution and to Mr Brighouse, the coroner, if any irregularity was brought home to him

THE CHEMISTRY OF WHISKY-AND-SODA

HOWEVER the fact may be deplored, whisky mixed with soda water is a very popular drink In Pickwickian times the favourite stimulant was brandy and water, later it was whisky and water, and now plain water is very generally replaced by aerated water The popularisation of aerated waters has undoubtedly had much to do with encouraging the drinking of whisky There are many persons who cannot drink plain whisky and water who will drink, perhaps with indiscreet relish, the same spirit mixed with sparkling water *The Scotchman or the connoisseur of whisky, not* necessarily synonymous terms, on the other hand, invariably prefers plain water with the spirit, and regards the admixture of soda water as a means of spoiling the æsthetic qualities of the whisky But in the one case flavour is sought after, while in the other merely an agreeably stimulating fluid is desired Some persons believe that soda water reduces the intoxicating effect of the spirit but probably an effervescing alcoholic liquid, judging from champagne, is more easily diffusible than a still liquid It is well known, at any rate, that very often when plain whisky and water disagree and sometimes give rise to a feeling of sickness, the substitution of effervescent *water has a quite different effect* There seems to be little doubt that some explanation of this is afforded by the fact that alcohol will dissolve three times as much carbonic acid gas as water will dissolve Alcohol would thus convey more gas to the stomach and carbonic acid gas in solution admittedly promotes the chemical processes of digestion and acts as a sedative in the stomach Champagne is well known to be useful in sickness in allaying irritability of the stomach by virtue of the carbonic acid gas it contains Apart therefore from the pleasing sparkling qualities of aerated water and its sharp, agreeable taste there would appear to be a sound physiological reason why whisky with soda water is preferred by the many to whisky with plain water

THE CLIMATIC ELEMENT IN THE TREATMENT OF PULMONARY TUBERCULOSIS

THE history of the treatment of pulmonary tuberculosis is an interesting and familiar one Apart from the countless drugs which have been from time to time vaunted as "cures" of the disease, warm climates, cold Alpine resorts, sea voyages, and residence in various parts of the globe have all had their supporters as suitable and desirable, if not indispensable, elements for the treatment of consumption Within the last few years, however, the results obtained in the sana*toriums in this country have led many physicians to believe* that climate does not hold such an invaluable position in the therapeutics of pulmonary disease as was formerly insisted upon The site of a sanatorium is all important, but evidence is accumulating to show that it is not absolutely necessary to banish a sufferer from pulmonary tuberculosis from his country and friends and to send him for months or years to the colonies or foreign countries On the other hand, *there is reason to believe that treatment in this country* has certain advantages, especially to those whose circumstances render it imperative that they should subsequently live in England The treatment is then carried on under the same climatic influences as those to which they will be subsequently subjected and they will not be forced to accustom themselves to the manner of living followed in other countries The paper which we publish in another column on "Results Obtained at the Mundesley Sanatorium in the Treatment of Pulmonary Tuberculosis," by Dr F W Burton Fanning and Mr W J Fanning, demonstrates the very satisfactory results which have been obtained in the Mundesley Sanatorium One paragraph in this communication is well worthy of attention Several patients on leaving the sanatorium went to various foreign health resorts, more or less renowned for the treatment of consumption The subsequent progress *of these patients was closely watched and in no single* instance was the course of the disease materially different after going away from what it would presumably have been had the patient remained in his own country We do not wish to imply that many foreign health resorts are not excellent places to which tuberculous patients may be sent if other circumstances permit, but the results of the English sanatoriums offer great hopes to those patients who are not able, from financial or family reasons, to go abroad In short, it appears that in the treatment of many cases where foreign residence would not long ago have been considered an essential step, equally satisfactory results may be obtained in this country We thoroughly agree, however, with the writers of the paper that there is one class of consumptive for whom a better climate than England can be found—namely, those who suffer from old standing pulmonary tuberculosis with defective circulations and inability to stand cold, catarrhal symptoms, and perhaps with affection of the kidneys and other internal organs. For such subjects a milder climate is indicated.

THE RAILWAY DISASTER IN PARIS

THE imagination could hardly paint anything more awful than the disaster which happened on the underground electric railway in Paris on August 8th The occurrence has certainly no parallel in the history of electric railways and the confidence of the public has naturally sustained a shock in regard to the security of this mode of travelling It cannot be gainsaid that now and again evidences of the fearful results that might arise through a diversion of the electric potentialities on electric railways have presented themselves We have written strongly in these columns, and more than once, on the risks to human life which "short circuiting" may involve and on the *extreme measures which should be adopted to* prevent the all powerful electric current from taking the short path The "boxes" in our streets catch fire, "leads" in the house get hot and cables fuse on the railways and tramways—all through short circuiting being established by a defect in the insulation Short-circuiting is, in fact, the greatest source of anxiety to the electrical engineer, and however well the insulation be done various causes may be at work conspiring to its breakdown. The disaster in Paris seems to have been primarily due *to an attempt to push* to the terminus a train on which admittedly the motor was "working badly." Passengers in this train had been advised to get out, but it appears that trains loaded with a human freight were employed to get the broken-down train to the end of the journey. There is little doubt, therefore, that the defective motor was the cause of a disastrous short-circuiting, with the result that the train and the succeeding trains caught fire in the tunnel. Stifling fumes arose, the electric lights, of course, were extinguished, and the whole electric system became a jumble of fused wires. The mental agony of the victims thus entombed must have been terrible. The disaster has cost over 80 lives and a black shadow of grief has overspread the French capital. It is to be hoped that the official inquiry, which must necessarily ensue, will clear up the actual cause of the calamity, at which we have made a confident surmise, and that the awful lesson which such an inquiry is bound to teach will not be lost to the world.

MR. BURDETT-COUTTS ON THE ARMY MEDICAL VOTE.

WE have received a printed copy of the speech made by Mr. Burdett Coutts, M.P., in the House of Commons on August 3rd, on the vote for the Army Medical Establishment. From this it would appear that his speech on that occasion was much longer, more important, and more carefully thought out than would be gathered from a perusal of the published reports of it which appeared in the daily press. We have no desire to reopen a public controversy of a very painful character, but some comments on our part seem to be called for. To begin with, we may say that, after having carefully read and considered Mr. Burdett-Coutts's recent speech, we are quite in sympathy and agreement with a great deal that is contained in it. It was as to the time, form, and method which were adopted and followed by Mr. Burdett-Coutts with the view of arousing public attention at the beginning that exception was taken. THE LANCET was never among those who sought to stifle inquiry into the deplorable circumstances set forth in the *Times*, the publication of which naturally gave rise to an almost universal feeling of indignant dismay. As time went on, and all the facts were elicited as to the actual conditions which brought about those deplorable occurrences, it became more and more apparent how very wide of the mark were many of the allegations and speculations that had been put forward. There is no need, however, to go into all this now. We dealt with the whole subject and with the needs and reform of the Army Medical Service, together with measures for the coöperation of the civil profession in time of war, in a series of articles at the time and are glad to think that much of what we then suggested is now being done. Without agreeing with every word that Mr. Burdett-Coutts said, we consider that he made an able and important statement which evidently impressed Mr. Brodrick not a little.

ECTOPIC (INTERSTITIAL) PREGNANCY COMPLICATING UTERINE PREGNANCY.

THE complication of uterine by ectopic pregnancy is very rare. In the *New York Medical Journal* of June 27th Dr. J. B. Morrison has published a case which derives additional interest from the fact that the ectopic pregnancy was interstitial. A woman, aged 35 years, who had had one child 11 years before and since then four abortions, came to him on Sept. 4th, 1902, saying that she had had a miscarriage on the previous day. She produced a fœtus of about eight weeks' development which had come away. The uterus was large, of about the size of an orange. On the right an ovoid mass one-half of the size of the uterus and continuous with it was felt. It was thought to be a mural fibroid or an old inflammatory lesion, perhaps a pyosalpinx adherent to the uterus. The cervix was soft and admitted the tip of the index finger. Contrary to advice the patient went away to the country. After 15 days she returned with a history of chill, fever for two or three days, and a foul discharge. Under anæsthesia the uterus was curetted. Some clots and shreds of decidua were removed and hot permanganate of potassium solution was used for irrigation. Two hours later she had a rigor and a temperature of 105° F. In the afternoon there was another chill and the temperature rose from 102° to 105·5°. Agonising pain developed in the position of the right tube and ovary. Morphine was given and cold was applied. The temperature fell to 101°, but on the following morning it rose again to 105° and the pain became as intense as ever and for the first time paroxysmal. Tenderness rendered examination almost impossible. The symptoms pointed to acute peritonitis but the facial aspect between the paroxysms was good, the respiration was not shallow, and the pulse ranged between 88 and 100. The history seemed to negative extra-uterine pregnancy. For two days the temperature ranged between 102° and 104° and the pain was controlled by morphine. On the fourth morning profuse uterine hæmorrhage occurred and the abdominal rigidity disappeared. The mass on the right of the uterus had diminished by one-half and during the examination a fœtus of from 10 to 12 weeks' development was expelled. Under anæsthesia the cervix was dilated. The interior of the uterus was everywhere smooth, but on the right the finger passed into a cavity a little larger than an egg, to the edges of which pieces of tissue appeared to be adherent. On the floor the finger slipped over a smooth mass which proved to be the placenta. As much of it as possible was removed and the cavity was irrigated. The pain ceased entirely. The irrigation was repeated daily for five days and several pieces of placenta came away. The temperature fell and for five days ranged between 99° and 100°. There was a serosanguineous discharge. Beckman divides cases of interstitial gestation into two groups: (1) tubo-uterine, in which the communication with the uterine cavity persists, resulting in early abortion into the uterus; and (2) true interstitial, in which the ectopic gestation is separated from the uterine cavity by a muscular septum and the sac ruptures into the peritoneal cavity or uterus. Dr. Morrison's case evidently belonged to the second class. The shreds felt at the orifice of the cavity were probably the remains of the ruptured septum. Perhaps the curetting, by weakening the septum as well as by producing uterine contractions, predisposed to the rupture. Before this occurred the diagnosis was practically impossible.

THE LANCASHIRE COUNTY COUNCIL AND VACCINATION.

AT the meeting of the Lancashire County Council held at Preston on August 6th the following motion, which was recommended by the public health committee, was discussed:—

> (*a*) That primary vaccination should be made compulsory; (*b*) that revaccination at or about the age of 12 years should be made compulsory; (c) that the control of the carrying out of the Vaccination Acts should be transferred from the boards of guardians to the county councils; and (*d*) that greater facilities for the supply of pure glycerinated lymph should be afforded.

Mr. R. Sephton, the chairman of the committee, in proposing the motion said that the large number of cases of small-pox made additional measures necessary and there seemed to be no doubt that efficient vaccination was the only trustworthy preventive. He stated that out of 416 cases reported during the quarter 280 patients had been vaccinated and there were 11 deaths, while of 109 non-vaccinated patients 15 died. An amendment was proposed by Alderman Snape referring the motion for further consideration. "He thought it would be unwise to adopt a series of such extremely drastic proposals, especially when it was remembered that a large number of people conscientiously objected to vaccination." The chairman, Sir John Hibbert, also demurred to the motion and the amendment was carried. It is a courteous euphemism to speak of the objections to vaccination as they are ordinarily presented to the magistrates' attention as "conscientious," as they are so often the result of ignorance or a contrary spirit. There are some people who are separated from their more "level-headed" neighbours by a peculiarity of mental constitution which renders them apt to take up with odd notions about many things besides vaccination and to be marked by many eccentricities, most of which may be harmless. If the possible consequences were not so serious the country could afford to let them revel in their fads to their hearts' content, but when their doing so is a constant danger to the health and the lives of the community it becomes a serious question whether the comparatively small number of objectors should be allowed to possess a weapon so dangerous.

THE RESULTS OF THE SURGICAL TREATMENT OF TUMOURS OF THE BRAIN.

Professor M. Allen Starr of New York has published in the *Journal of Mental and Nervous Diseases* for July a valuable paper summarising the results of the surgical treatment of tumours of the brain as practised during the past ten years and drawing the conclusions necessary for our future guidance in regard to diagnosis and treatment. In 1893 he was able to collect from literature 70 cases of tumour of the brain in which an operation had been undertaken. As a knowledge of the possibility of operation became more widespread, says Professor Starr, and the technique of the surgery of the brain more perfect reports of such operations grew more frequent and it was possible to collect 365 cases up to Jan. 1st, 1903. The results of operation in these 365 cases are tabulated as follows :—

Results of operation.	Number of cases of cerebral tumour.	Number of cases of cerebellar tumour.
Tumour removed and patient recovered	152	16
Tumour removed and patient died	51	8
Tumour found but not removed	21	6
Tumour not found	91	20
Total	315	50

There are two elements which render the chances of success in the operation for tumours of the brain better at present than formerly. First, the accuracy of diagnosis is more possible. Given a history of a slowly progressing disease, with symptoms of headache, vomiting, vertigo, sensations of cerebral discomfort, progressive emaciation and feebleness, and optic neuritis, and the only probable hypothesis is the existence of a tumour of the brain. Hence the diagnosis of the nature of the disease is not difficult. Secondly, the possibility of localising tumours has also become more definite within the last 20 years. The occurrence of such symptoms as aphasia, local spasm and hemiplegia, hemianopsia, cerebellar staggering, and mental disturbance would help to locate the tumour, while the absence of these localising symptoms would make it evident that the tumour was inaccessible. The use of electrical saws has during the past three years largely superseded the use of the trephine, gouge, and chisel, and access to the brain can now be obtained in from six to eight minutes after the incision through the scalp has been made. Usually, adds Professor Starr, the brain can be exposed within ten minutes of the time of the beginning of the operation, whereas in older methods from 18 to 25 minutes were often expended in this part of the operation. Moreover, excision of a tumour which may reach to a depth of one or two inches below the cerebral surface, is now freely attempted and performed, and he considers that the statistics of the next ten years will show a very much greater percentage of successes than do the statistics up to the present time. The operation for cerebellar tumours is attended with great difficulty and danger. The surface of the lateral cerebellar lobes accessible to the trephine or the saw is very rarely the seat of a cerebellar tumour. Such tumours lie either in the middle lobe of the cerebellum, directly beneath the tentorium, a point which cannot be reached from the lower surface of the cerebellum, or else they lie in the sulci between the cerebellum and the pons and medulla oblongata upon the base of the brain, a point which is equally inaccessible. For this reason, concludes Professor Starr, failures are numerous in operations for cerebellar tumour, and after a considerable experience he concludes that it seems futile to attempt this operation. Occasionally a tumour may develop in one part of the brain and give rise to localising symptoms of a misleading character referable to another part of the brain. The local symptoms are therefore not infallible in their indication and this may occasionally be a cause of failure. Soft and infiltrating tumours such as gliomata are difficult to remove entirely, and this variety of tumour is liable to recur even if removed in part. The dangers of hæmorrhage and of meningitis are less dreaded to-day than formerly, proper asepsis preventing the latter complication in all cases.

THE HOME FOR EPILEPTICS AT MAGHULL.

THE fourteenth annual report of the Home for Epileptics at Maghull, near Liverpool, includes the history and medical statistics of the institution for the year ending Dec. 31st, 1902. At the commencement of the year there were 138 patients under care and treatment and at the end of the year there were 174. The class of patients received includes persons suffering from epilepsy but not from insanity. Epileptics deemed to be dangerous to themselves or others are not admitted. Instruction is given to the younger patients who are provided with the advantages of a regular day school and winter evening continuation classes. A local fire brigade, composed chiefly of patients, has been in existence for some years and recently on the occasion of a fire occurring in a barn attached to a farmhouse on the adjoining estate, the members of the fire brigade proved themselves efficient and quick in extinguishing the fire and in saving the main farm building itself. The committee of management now owns or rents about 100 acres of land where the patients are trained in agriculture. The farm account showed a profit for the year of £150, a fact which seems to show that by utilising the labour of the inmates the home can be made in a measure self-supporting. The grounds at Harrison Home—a new building erected about a year ago for first-class patients—have been suitably laid out with ample tennis and croquet lawns, shrubbery, and flower beds. A billiard-room and other comforts of a first-class home are provided. The male patients are trained to steady work in the fields and gardens or about the houses and the female patients to house and laundry and garden work. The patients are also trained in basket-making, joinery, choir singing, and brass band music The subjects taught in the day school and in the evening continuation classes include reading, writing, arithmetic, drawing, singing, history, geography, wood-carving, drill, and kindergarten work. The medical report states that amongst the 94 female patients the total number of fits recorded during the year was 10,103. Of these 5212 were slight attacks. The more

THE NEW WATER-SUPPLY OF MARGATE.

THE municipal authorities of Margate have now dealt successfully with two leading requirements of sanitation: they have provided for the effectual disposal of the sewage of the town and for an abundant supply of pure water for drinking purposes. In 1890 a comprehensive, and what has since proved to be an efficient, main drainage scheme was provided and on August 6th last the new public water-supply for the town was inaugurated by the mayor. It had been found that the new sewage works caused heavy demands upon the water-supply and not only did the existing supply run short but its quality for drinking purposes seriously deteriorated. It became evident that as the wells *were more vigorously pumped to meet increasing needs percolation* of the sea water happened, with the result that the drinking water of Margate soon assumed a brackish taste and the Tivoli, the original source of supply, was found to contain as much mineral salts as 172·69 grains per gallon. Attempts were made, presumably for economical reasons, to obtain auxiliary supplies by sinking wells in the neighbourhood of the existing works but with limited success, while no appreciable advance was made as regards quality. The water was brackish, as might be supposed seeing that the water line was reduced so low that the wells, at any rate in the summer season, were nearly always pumped below the sea-level and frequently they were exhausted.

Such a condition of things was obviously a great reproach to a town like Margate which enjoys a deserved reputation in regard to the tonic and invigorating properties of its air. *Strictly speaking, to describe a place as a health resort with* the knowledge that its water-supply was not only short but objectionable in quality would be incongruous. This aspect of the question was, however, not at first seriously appreciated by the inhabitants of the town nor did they see how their interests could be affected. Happily, however, ignorance as to the serious issues which such a position might involve disappeared, such opposition to reform as existed was broken down, and the authorities at Margate may be warmly congratulated on having brought a scheme promoted in the best interests of the town to a satisfactory conclusion. A considerable amount of prejudice and misunderstanding existed, for when the facts were placed before the electorate, together with the proposal to go to an abundant catchment area some 15 miles away from the town in the direction of Canterbury and a poll was taken in February, 1901, the result was that the *scheme* was *rejected.* A year later, *owing* to a well-organised movement, in which the representatives of the medical profession at Margate had a considerable share, the owners and ratepayers gave their consent by a substantial majority. We heartily congratulate the medical men at Margate upon this important sanitary triumph which after much uphill work they helped to secure. The Wingham scheme, as it is called, was proposed by Mr Albert Latham, the borough engineer, after he had received an instruction from the corporation to inquire into the subject. This scheme gained the approval of the well-known water engineers, Mr. Charles Hawksley and Mr. Edward M. Eaton, and of the geologist, Mr. W. Whitaker, who in their report wrote: "We consider that this scheme will afford an ample supply of water, good and admirable in quality, and sufficient in quantity to meet the growing demands of Margate for many years to come." Subsequently the Act of Parliament authorising the scheme received the Royal Assent on August 6th, 1902, so that the completion of the undertaking has, officially speaking, occurred exactly within a year of the formal leave to commence work. As a matter of fact, the works were started on Oct. 21st, 1902, and the new water was supplied to Margate for the first time on July 16th, 1903. The entire cost will be about £120,000.

The village of Wingham, where the new pumping station is situated, lies near the outcrop of the line of chalk hills extending from Canterbury to Dover. The new pumping station is about a mile south of the village and is on the main road from Wingham to Adisham railway station on the South-Eastern Railway. Behind the pumping station the hills continue to rise until the ridge is reached at a distance of four miles, the water from t[illegible] to feed the adits at the st[illegible] *yards of adits* have been driven [illegible] per day are furnished by them. Powers, however, have been obtained for driving no less than three miles of adits if necessary in order that the *supply may be abundant both for* present and future requirements. The amount required for the supply of Margate at the height of the season (at the present time) is 1,250,000 gallons per day. The well at the pumping station is sunk to ordnance datum, which is 130 feet below the surface of the ground, and the adits are driven in two directions at that level, rising slightly as they penetrate the ground, running away from the well. It is stated that within a week after the heavy pumping by the contractors' pumps had ceased for the purpose of driving the adit the water rose to within two feet of the height at which it had stood before this heavy pumping was started. This pumping was continued for six months. Special precautions have been adopted by the corporation to prevent the pollution of the environment. It is, however, confidently felt that there is not much risk on this head as the district forming the *watershed is very thinly populated. The rising main from* the pumping station at Wingham to Margate is 14 miles in length and 18 inches in diameter, this size being considered equal to the demands of the town for many years. The main is carried across the river Stour by being slung to the new bridge recently erected over that river at Pluck's Gutter by the local authorities, including th[illegible] supply from [illegible] tion entered [illegible] which lie along the route of the main. There are thus 18 parishes and a high and low service tank have been erected for the supply of these parishes, a scheme which involves the laying out of 30 miles of mains, of which nine miles have already been laid, the rest being in progress. The quality of the new water-supply is quite satisfactory according *to both the results of bacteriological and chemical analysis,* the former having been undertaken by Dr. Klein and the latter by Mr. Sidney Harvey, F.I.C., the analyst to the city of Canterbury and to the boroughs of Dover, Faversham, and Margate. The water is of the usually pure type derived from the chalk and shows an irreproachable organic purity similar to that of the water supplied from chalk wells by the Kent Water Company. The hardness is nearly all removed by boiling, for out of a total of 21·3 grains per gallon only 2 2 grains remain after boiling. Altogether the new water-supply to Margate belongs to the class of excellent drinking water.

Considerable praise is due to those who were responsible for carrying out the engineering arrangements, to those representing the corporation who successfully piloted the Bill through Parliament, and to those who (in spite of the *opposition* and prejudice which they had to face) persevered in the best interests of the public health in bringing the scheme to an accomplished fact. Margate may be congratulated upon having removed a source of reproach upon its health which sooner or later would have seriously militated against the prosperity which it enjoys.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are the awards recommended by the committee of distribution for the year 1903:—

GENERAL HOSPITALS.

Charing Cross Hospital, £1083 6s. 8[illegible]
German [illegible]
£1121 5s [illegible]
Italian [illegible]
London [illegible]
£563 15s [illegible]
London [illegible]
£953 6s. [illegible] Miller Hospital and
Royal [illegible] London Hospital,
£476 13s. [illegible] n's Jubilee Hospital,
£151 13s [illegible] t. George's Hospital,
£1137 10s [illegible] £276 5s.; St. Mary's
Hospital, [illegible]; Seamen's Hospital
Society, [illegible] Convalescent Home,
£2415 1[illegible] University College
Hospital, [illegible] 1s 8d.; West Ham
Hospital, £563 6s. 8d., West London Hospital, £1170, Westminster Hospital, £1451 13s. 4d.

CHEST HOSPITALS.

City of London Hospital for Diseases of the Chest, Victoria-park, £1105; Hospital for Consumption, Brompton £1733 6s. 8d.; Mount Vernon Consumption Hospital, Hampstead, £780, Royal Hospital for Diseases of the Chest, *City road, £487 10s.; Royal National Hospital* for Consumption (Ventnor), £379 3s. 4d.

CHILDREN'S HOSPITALS.

Alexandra Hospital for Hip Disease, W.C., £303 6s. 8d.; Banstead Surgical Home, £27 1s. 8d.; Barnet Home Hospital, £48 15s.; Belgrave Hospital for Children, S.W., £113 15s.; Cheyne Hospital for Incurable Children, S.W., £119 3s. 4d.; East London Hospital for Children, Shadwell, E., £931 13s. 4d.; Evelina Hospital for Sick Children, Southwark, S.E., £216 13s. 4d.; Home for Incurable Children, Maida-vale, W.C., £81 5s.; Home for Sick Children, Sydenham, S.E., £140 16s. 8d.; Hospital for Sick Children, Great Ormond-street, W.C., £975; North-Eastern Hospital for Children, Hackney-road, N.E., £390; Paddington-green Hospital for Children, W., £297 18s. 4d.; St. Mary's, Plaistow, E., £281 13s. 4d.; St. Monica's, Brondesbury, N.W., £86 13s. 4d.; Victoria Hospital for Children, King's-road, Chelsea, S.W., £476 13s. 4d.; Victoria Home, Margate, £48 15s.; Hospital for Hip Disease, Sevenoaks, £48 15s

LYING-IN HOSPITALS.

British Lying-in Hospital, Endell-street, W.C., £16 5s.; City of London Lying-in Hospital, City-road, E.C, £100; Clapham Maternity Hospital, £21 13s. 4d.; East-end Mothers' Home, £75 16s. 8d.; General Lying-in Hospital, Lambeth, S.E., £32 10s.; Queen Charlotte's Lying-in Hospital, Marylebone-road, W., £476 13s. 4d.

HOSPITALS FOR WOMEN.

Chelsea Hospital for Women, S.W., £379 3s. 4d.; Hospital for Women, Soho-square, W., £130; Grosvenor Hospital for Women and Children, Vincent-square, S.W., £162 10s.; New Hospital for Women, Euston-road, W.C., £325; Royal Hospital for Children and Women, Lambeth, S.E., £216 13s. 4d.; Samaritan Free Hospital, Marylebone-road, W., £438 15s.

OTHER SPECIAL HOSPITALS.

Cancer Hospital, Brompton, S.W., £325; Middlesex Hospital, Cancer Wing, £325; London Fever Hospital, Islington, N., £158 6s. 8d.; Gordon Hospital for Fistula, Vauxhall Bridge-road, S.W., £21 13s. 4d.; St. Mark's Hospital for Fistula, City-road, E.C., £130; National Hospital for Diseases of the Heart, Soho-square, W., £86 13s. 4d.; Female Lock Hospital, Harrow-road, W., £227 10s.; Hospital for Epilepsy, Paralysis, and Other Diseases of the Nervous System, Regent's-park, N.W., £32 10s; National Hospital for the Paralysed and Epileptic, W.C., £1148 6s. 8d.; West-End Hospital for Diseases of the Nervous System, £216 13s. 4d.; Central London Ophthalmic Hospital, Gray's-inn-road, W.C., £184 3s. 4d.; Royal Eye Hospital, St. George's-circus, S.E., £313 3s. 4d.; Royal London Ophthalmic Hospital, City-road, E.C., £942 10s.; Royal Westminster Ophthalmic Hospital, Charing-cross, W.C., £184 3s. 4d.; Western Ophthalmic Hospital, Marylebone-road, W., £54 3s. 4d.; City Orthopædic Hospital, Hatton-garden, E.C., £232 18s. 4d.; National Orthopædic Hospital, Great Portland-street, W., £178 15s; Royal Orthopædic Hospital, Oxford-street, W., £81 5s.; Royal Sea Bathing Hospital, Margate, £325; St. John's Hospital for Diseases of the Skin, £54 3s. 4d.; St. Peter's Hospital for Stone, Covent-garden, £92 1s. 8d.; Central London Throat and Ear Hospital, Gray's-inn-road, W.C., £54 3s. 4d.; Hospital for Diseases of the Throat, Golden-square, W., £108 6s. 8d.; London Throat Hospital, Great Portland-street, W., £32 10s.; Metropolitan Ear, Nose, and Throat Hospital, Grafton-street, W., *nil*; Royal Ear Hospital, Frith-street, W., £10 16s. 8d.; Dental Hospital of London, Leicester-square, W.C., £195; National Dental Hospital, 149, Great Portland-street, W., £43 6s. 8d.

CONVALESCENT HOSPITALS.

Metropolitan Convalescent Institution, Sackville-street, W., £704 3s. 4d.; Bexhill Convalescent Home, Sackville-street, W., £379 3s. 4d.; All Saints' Convalescent Hospital, Eastbourne, £433 6s. 8d.; Ascot Priory Convalescent Home, £70 8s. 4d.; Barnet, £48 15s.; Brentwood, for Children, £13; Charing Cross Hospital Convalescent Home, Limpsfield, £99 13s. 4d.; Chelsea Hospital for Women Convalescent Home, St. Leonards, £43 6s. 8d.; Deptford Medical Mission Convalescent Home, Bexhill, £32 10s; Mrs. Gladstone Convalescent Home, Mitcham, £65; Friendly Societies' Convalescent Home, Dover, £75 16s. 8d.; Hahnemann Convalescent Home, Bournemouth, £48 15s; Hanwell Convalescent Home, £21 13s. 4d; Herbert Convalescent Home, Bournemouth, £21 13s. 4d.; Herne Bay Baldwin-Brown Convalescent Home, £32 10s.; Homœopathic Convalescent Home, Eastbourne, £21 13s. 4d.; King's College Hospital Convalescent Home, Hemel Hampstead, £70 8s. 4d.; Mrs. Kitto's Convalescent Home, Reigate, £65; Mary Wardell Convalescent Home for Scarlet Fever, £97 10s.; Morley House Convalescent Home for Working Men, £189 11s. 8d.; Police Seaside Home, Brighton, £59 11s. 8d.; St. Andrew's Convalescent Home, Clewre, £130; St Andrew's Convalescent Home, Folkestone, £195; St. John's Home for Convalescent and Crippled Children, Brighton, £37 18s. 4d.; St. Joseph's Convalescent Home, Bournemouth, £70 8s. 4d.; St. Leonards-on-Sea Convalescent Home for Poor Children, £86 13s. 4d.; St. Mary's Convalescent Home, Shortlands, £21 13s. 4d; St. Michael's Convalescent Home, Westgate-on-Sea, £37 18s. 4d.; Seaside Convalescent Hospital, Seaford, £108 6s. 8d.; Richmond House, Worthing, £27 1s. 8d.

COTTAGE HOSPITALS.

Acton Cottage Hospital, £75 16s. 8d.; Beckenham Cottage Hospital, £86 13s. 4d.; Blackheath and Charlton Cottage Hospital, £86 13s. 4d.; Bromley, Kent, Cottage Hospital, £130; Bushey Heath Cottage Hospital, £48 15s.; Canning Town Cottage Hospital, £54 3s. 4d.; Chislehurst, Sidcup, and Cray Valley Cottage Hospital, £86 13s. 4d.; Coldash Cottage Hospital, £19 10s.; Eltham Cottage Hospital, £65; Enfield Cottage Hospital, £75 16s. 8d.; Epsom and Ewell Cottage Hospital, £70 8s. 4d.; Hounslow Cottage Hospital, £48 15s.; Livingstone Cottage Hospital, £97 10s.; Mildmay Cottage Hospital, £32 10s.; Reigate and Redhill Cottage Hospital, £124 11s. 8d.; Sidcup Cottage Hospital, £32 10s.; Tilbury (Passmore Edwards) Cottage Hospital, £32 10s.; Willesden Cottage Hospital, £140 16s. 8d.; Wimbledon Cottage Hospital, £65; Woolwich and Plumstead Cottage Hospital, £59 11s. 8d.

INSTITUTIONS.

Bolingbroke Hospital, £249 3s. 4d.; Establishment for Gentlewomen, Harley-street, £119 3s. 4d.; St. Saviour's Hospital and Nursing Home, £130; National Sanatorium for Consumption, Bournemouth, £97 10s.; Invalid Asylum, Stoke Newington, £48 15s.; Firs Home, Bournemouth, £21 13s. 4d.; St. Catherine's Home, Ventnor, £27 1s. 8d.; Friedenheim Hospital for the Dying, £325; Oxygen Home, Fitzroy-square, £37 18s. 4d.; Santa Claus Home, Highgate, £59 11s. 8d.; St. John's Hospital, Lewisham, £162 10s.; Home for Consumptive Females, *nil.*

DISPENSARIES.

Battersea Provident Dispensary, £92 1s. 8d.; Billingsgate Medical Mission, £21 13s. 4d.; Blackfriars Provident Dispensary, £21 13s. 4d.; Bloomsbury Provident Dispensary, £14 1s. 8d.; Brixton, &c., Dispensary, £56 6s. 8d.; Brompton Provident Dispensary, £17 6s. 8d.; Camberwell Provident Dispensary, £65; Camden Town Provident Dispensary, £14 1s. 8d.; Chelsea, Brompton, and Belgrave Dispensary, £57 8s. 4d.; Chelsea Provident Dispensary, £13; Child's Hill Provident Dispensary, £13; City Dispensary, £54 3s. 4d.; City of London and East London Dispensary, £16 5s.; Clapham General and Provident Dispensary, £23 16s. 8d.; Deptford Medical Mission, £23 16s. 8d.; Eastern Dispensary, £32 10s.; East Dulwich Provident Dispensary, £37 18s. 4d.; Farringdon General Dispensary, £43 6s. 8d.; Finsbury Dispensary, £48 15s.; Forest Hill Dispensary, £43 6s. 8d.; Greenwich Provident Dispensary, £27 1s. 8d.; Hackney Provident Dispensary, £13; Hampstead Provident Dispensary, £43 6s. 8d.; Holloway and North Islington Dispensary, £54 3s. 4d.; Islington Dispensary, £59 11s. 8d.; Kensal-town Provident Dispensary, £10 16s. 8d; Kensington Dispensary, £81 5s.; Kilburn, Maida-vale, and St. John's-wood Dispensary, £43 6s. 8d.; Kilburn Provident Medical Institution, £28 3s. 4d.; London Dispensary, Spitalfields, £17 6s. 8d.; London Medical Mission, Endell-street, £108 6s. 8d.; Metropolitan Dispensary, £56 6s. 8d.; Notting-hill Provident Dispensary, £14 1s. 8d.; Paddington Provident Dispensary, £32 10s.; Portland Town Dispensary, £21 13s. 4d.; Public Dispensary, Clare Market, W.C., £43 6s. 8d.; Queen Adelaide's Dispensary, £29 5s; Royal General Dispensary, £27 1s. 8d.; Royal Pimlico Provident Dispensary, £54 3s. 4d.; Royal South London Dispensary, £52; St. George's and St. James's Dispensary, £54 3s. 4d.; St. George's, Hanover-square, Provident Dispensary, £32 10s.; St. John's-wood Provident Dispensary, £45 10s; St. Marylebone General Dispensary, £41 3s. 4d.; St. Pancras and Northern Dispensary, £34 13s. 4d.; South Lambeth, Stockwell, and North Brixton Dispensary, £43 6s. 8d.; Stamford-hill, Stoke Newington, Dispensary, £65; Tower Hamlets Dispensary, £48 15s.; Walworth Provident Dispensary, £16 5s.; Wandsworth-common Provident Dispensary, £10 10s. 8d.; Westbourne Provident Dispensary, £16 5s.; Western Dispensary, £59 11s. 8d.; Western General Dispensary, £135 8s. 4d.; Westminster General Dispensary, £41 3s. 4d.; Whitechapel Provident Dispensary, £28 3s. 4d.; and Woolwich Provident Dispensary, £19 10s.

Looking Back.

FROM

THE LANCET, *SATURDAY*, AUGUST 13, 1825.

FROM

LECTURES

ON THE

PRINCIPLES AND PRACTICE OF PHYSIC,

BY DR. ARMSTRONG.

Theatre of Anatomy, Webb Street.

The following is an Abstract[1] *of Dr. Armstrong's Lectures on Chronic Affections of the Fauces, Air Passages, Lungs, and Heart.*

Pulmonary Consumption.

Dr. ARMSTRONG remarked, that pulmonary consumption was most common in individuals under twenty-five years of age, but that he had seen many cases between that age and thirty-five, and several at a much later period of life than the last-mentioned. He considered the delicacy of young persons as the cause by which they were most predisposed, and observed, that two circumstances were almost always found to concur in the production of pulmonary consumption, namely, a breaking up or giving way of the general strength, and the application of what is called cold, under that condition of the body. He adduced several cases in proof of this assertion, some of which arose in this manner from copious bloodletting, some from spare diet, some from mental anxiety, some from over-exertion, some from night-watching, some from disorders which interrupted the digestion, and others from the like occasions. He said that the same reasoning was applicable to the production of the disease in the lower animals, for that sheep, young horses, and rabbits, being badly fed and exposed to cold at the same time, were apt to become consumptive. Dr. ARMSTRONG considered this view of the subject as of the highest importance to society in a preventive point of view, and especially to those families in which the tendency to consumption hereditarily prevailed; for he contended that this complaint might be prevented in such families by maintaining the general strength through a nutritious diet and other regimenal points, and by giving tone to the surface of the body, first by tepid and next by cool sponging or ablution, but in this variable climate he strongly recommended the use of thin flannel, even in the summer, and of fleecy hosiery in the winter and spring, next the surface, where the least suspicion of, or tendency to phthisis existed The development of phthisis, according to his observation, was always preceded by some change in the functions of the skin, which became more faded than natural, and by some consentaneous irritation of the internal mucous membranes, especially of the intestinal canal and of the bronchial passages, but he admitted that the local irritation which preceded the attack was occasionally in the pleura or lungs

---

[1] An excerpt only is transcribed.

Dr ARMSTRONG spoke in strong terms against the empirical use of mercury in the British metropolis for many supposed hepatic or duodenal affections, and was fully confident that, by breaking up the general strength, and by disordering the functions of the skin, it was a very common cause of inducing phthisis, aided by the operation of our changeable climate

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of London —Some indication of the remarkable changes as regards population which are taking place in the City of London may be gathered from the fact that on April 1st, 1891, the *night* population was 37,702, whereas in 1901 the night population had fallen to 26,923 But these figures convey a very misleading conception of the great importance of sanitary administration in the City of London as regards the health not only of the metropolis but of that vast migratory population which is dependent upon the City for a livelihood, one which inhabits an area far beyond the limits of what is called "Greater London" Perhaps one of the most important health functions to which the sanitary authority of the City can devote itself is the control of foodstuffs, and in this connexion we are glad to see that attention has recently been directed to the condition of the kitchens of restaurants Dr W Collingridge reports that out of 155 kitchens inspected 76 were in the basement, and although this is by no means uncommon in London generally it is obviously preferable that such places shall be in situations where abundance of light and air can be procured and where ventilation can be carried out by other means than through a street grating which acts as a variety of scraper for the foot passengers passing over it. It is not difficult to understand how food stored, although only for a short time, in these kitchens might be expected to contain bacteria of animal origin, and the fact that in 26 instances the water-closet opened or was ventilated directly into the kitchen is sufficient to make the public eschew such restaurants until these conditions are remedied We are told that in one case the lobby of the water closet was used for the storage of meat This question of the storage of food intended for human consumption does not receive as much attention as it deserves and we should be glad to see some by laws drawn up for regulating the position of pantries, &c., in all new houses The City has now followed the example set by Kensington and other London boroughs and appointed a woman sanitary inspector and the medical officer of health is well pleased with the work which she is doing A certain portion of this work has consisted in the inspection of ladies' waiting rooms at all the railway stations in the City and we wish that every sanitary authority throughout the country would have these conveniences for both sexes periodically inspected We are glad to see that Miss Safford, the newly appointed sanitary inspector to the City, has drawn the attention of employers to the importance of providing sanitary conveniences in offices, more especially those in which women are employed as typewriters and clerks. She states that in "the very large majority of these offices there is no sanitary accommodation provided for the women employed" Among other nuisances which obtain in the City those created by smoke are being vigorously attacked Dr Collingridge gives an interesting account of the removal of the remains of convicts who had died or been executed at Newgate Gaol By an order of the Home Secretary the remains of 92 persons were thus removed under the superintendence of the medical officer of health The experience gained by the exhumation referred to seems to have satisfied Dr Collingridge that the present method of dealing with the bodies of those who have undergone capital punishment is, to say the least of it, eminently unwholesome. It seems, however, from an interesting passage which is quoted in the report before us from a work on the law of burial that the bodies of murderers were at one time denied burial altogether, and when this prohibition was withdrawn it was enacted that the body of every murderer should either be dissected or hung in chains The present law upon this subject provides for an alternative to intramural burial and Dr Collingridge suggests that it might be taken advantage of We have no space to deal at all freely with the subject of the destruction of unsound food but it may be noted that 362 cartloads of such food were destroyed as trade refuse during 1902 Cases of ice cream poisoning occurred during the summer and in certain ice creams subsequently submitted to him Dr Klein discovered organisms which were highly pathogenic to guinea pigs There can be no doubt that much good is likely to accrue from the London County Council (General Powers) Act, 1902, which contains clauses as to the control of ice cream manufacture It is largely the conditions under which the materials are stored between boiling and freezing which are responsible for contamination of ices, an inference which is drawn from the fact that most of the pathogenic organisms discovered are non-sporing organisms and as such were likely to be destroyed by the boiling process Under the regulations now drawn up by the City corporation it is provided that freezing must take place immediately after boiling Dr Collingridge's interesting report also contains an account of the action taken by the corporation with regard to contaminated shell fish—a matter which has recently been the subject of discussion in these columns

The City of Birmingham —Dr Alfred Hill has now made 30 annual reports upon the health of the population of Birmingham, and in this his thirtieth and, we believe we are right in saying, farewell report he has the great satisfaction of being able to announce the fact that the death rate for 1902 was the lowest ever recorded for the city Not only has Dr Hill served Birmingham long and faithfully as medical officer of health, but he has also an unbroken record of 41 years' service for the city in the capacity of public analyst The population of Birmingham at the middle of 1902 was estimated at 528,181 and the following record of the inroads of death for the three years 1900–02 among the several age groups is sufficiently interesting to merit reproduction —

Under 1 year	222 7 per 1000
Between 1 and 5 years	27 5 ,,
,, 5 ,, 10	3 9 ,,
,, 10 ,, 15	2 1 ,,
,, 15 ,, 25	3 7 ,,
,, 25 ,, 45	9 2 ,,
,, 45 ,, 65	28 1 ,,
Over 65	93·4 ,,

As Dr Hill observes, the most important feature in this table is the toll exacted by death from the infant population of the city Scarlet fever was quite remarkably prevalent during 1902, no fewer than 5044 cases having been notified, a number which gave an attack rate of 9 39 per 1000 of the population The fatality rate for the year was 5 8 per cent The incidence of the disease varied materially in different wards of the city—i e, from 14 1 to 4 0 per 10 000 Dr Hill states that these figures send to show that scarlet fever is as much a disease of the healthy as of the unhealthy wards—i e, it bears no relation to what are generally regarded as insanitary conditions A large number of the cases notified were isolated in hospital, as many as 4534 cases having been thus dealt with. As regards pulmonary tuberculosis the death rates in the different wards ranged from 27 8 to 9 per 10,000, facts from which with those of previous years Dr Hill infers that "consumption is principally a disease of the less sanitary portions of the city where both the hygenic and social conditions are of inferior character" Dr Hill devotes considerable space to the housing question, and as to this he remarks "The most trying need of Birmingham at the present moment is better house accommodation for the labouring classes" He adds that houses of three or four rooms are being continually removed to make way for business premises, and as no additional houses of this type are erected there is a great difficulty in dealing with the housing question. He advises the city council to erect such accommodation under Part 3 of the Housing of the Working Classes Act. Dr. Hill thinks that consumption and certain other preventable diseases will never be stamped out until new healthy houses have been provided.

Salford County Borough.—Mr. Charles H. Tattersall reports that an outbreak of typhus fever occurred in Salford during 1902. There were altogether 49 cases and of these 15 died. The outbreak appears to have been set going, as usual, through the agency of unrecognised cases and it is not unlikely that the disease may have been introduced from Liverpool. It was only by means of a house-to-house inspection that the course of the disease was checked and the sanitary inspectors were instrumental in bringing to light several unrecognised cases. A teacher in one of the schools was attacked and as she lived in a house with other teachers employed in other schools it was deemed desirable to close all the schools with which such teachers were connected. Generally it was found that those attacked were living under overcrowded, dirty, and poverty-stricken conditions, but nine of the cases appear to have belonged to a class in which those conditions did not obtain. Three of these nine were employés of the corporation—i.e., a vanman, a nurse, and a wardmaid. Under the powers conferred upon Salford by its Improvement Act of 1899 24 samples of milk supplied to Salford were sent to Professor S. Delépine for bacteriological examination and 20·8 per cent. of such samples were found to cause tuberculosis. The farms from which these samples came were visited and the cows were examined. Of the five cows which had yielded the tuberculous milk two had already been slaughtered and milk from five additional cows with suspicious-looking udders was taken for examination. Four of these samples caused tuberculosis.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8257 births and 4139 deaths were registered during the week ending August 8th. The annual rate of mortality in these towns, which had been 13·5, 13·4, and 14·4 per 1000 in the three preceding weeks, declined to 14·3 last week. In London the death-rate was 13·0 per 1000, while it averaged 14·9 in the 75 other large towns. The lowest death-rates in these towns were 5·1 in Burton-on-Trent, 5·3 in Hornsey, 5·7 in Coventry, 6·2 in Southwark, 6 8 in Leyton, 7·1 in Barrow-in-Furness, 7·4 in Bournemouth, and 7 6 in Swansea; the highest rates were 21·0 in Wigan, 21·5 in Burnley, 22·7 in Ipswich, 23·8 in Grimsby, 24·3 in Sheffield, 24·8 in Birkenhead, and 26·6 in Bootle. The 4139 deaths in these towns last week included 717 which were referred to the principal infectious diseases, against 473, 532, and 591 in the three preceding weeks; of these 717 deaths 480 resulted from diarrhœa, 61 from whooping-cough, 57 from measles, 44 from diphtheria, 38 from scarlet fever, 29 from "fever" (principally enteric), and eight from small-pox. No death from any of these diseases was recorded in Hornsey, Hastings, Bournemouth, Devonport, Burton-on-Trent, Handsworth, Smethwick, Huddersfield, or Stockton-on-Tees; the highest death-rates from these principal infectious diseases were recorded in Walsall, Grimsby, Birkenhead, Bootle, Wigan, Warrington, Sheffield, and Newport (Mon.). The greatest proportional mortality from measles occurred in Ipswich, Stockport, and Sheffield; from diphtheria in Nottingham and Wallasey; from whooping-cough in Reading, Rochdale, Sheffield, and Newport (Mon.); from "fever" in Grimsby; and from diarrhœa in Grimsby, Birkenhead, Bootle, St. Helens, Warrington, Sheffield, and Rotherham. The mortality from scarlet fever showed no marked excess in any of the large towns. Small-pox caused one death in Birmingham, one in Liverpool, one in Manchester, two deaths in Halifax, one death in Leeds, and two deaths in Newcastle-on-Tyne, but not one in any other of the 76 large towns. The Metropolitan Asylums hospitals contained 48 small-pox patients on Saturday last, August 8th, against 71, 71, and 66 on the three preceding Saturdays; four new cases were admitted during last week, against seven, 12, and nine in the three preceding weeks. The number of scarlet fever patients under treatment in these hospitals and in the London Fever Hospital, which had been 1710, 1711, and 1726 at the end of the three preceding weeks, had further increased to 1771 at the end of last week; 216 new cases were admitted during the week, against 243, 229, and 237 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 115, 132, and 110 in the three preceding weeks, fell again last week to 107, and were 28 below the number in the corresponding period of last year. The causes of 39, or 0·9 per cent., of the deaths in the 76 large towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Salford, Bradford, Hull, Newcastle-on-Tyne, and in 48 other smaller towns; the largest proportions of uncertified deaths were registered in Northampton, Liverpool, and Bury.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 15·2, 15·4, and 14·7 per 1000 in the three preceding weeks, fell again to 14·6 per 1000 during the week ending August 8th and was 0 3 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·3 in Paisley and 11·6 in Aberdeen to 19·0 in Leith and 20·3 in Greenock. The 478 deaths in these towns included 34 which were referred to diarrhœa, six to "fever," six to scarlet fever, five to whooping-cough, five to measles, and four to diphtheria. No death occurred from small-pox during the week. In all, 60 deaths resulted from these principal infectious diseases last week, against 57, 62, and 63 in the three preceding weeks. These 60 deaths were equal to an annual rate of 1·8 per 1000, which was 0·1 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 22, 34, and 28 in the three preceding weeks, were again 28 last week, of which 21 occurred in Glasgow, four in Dundee, and three each in Edinburgh, Leith, and Greenock. The deaths referred to different forms of "fever," which had been three, six, and five in the three preceding weeks, rose again to six last week and included five in Glasgow. Four of the five fatal cases of measles, and four of the five fatal cases of whooping-cough occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 73, 79, and 69 in the three preceding weeks, fell last week to 54, and were nine below the number in the corresponding period of last year. The causes of three, or 0·6 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 16·0, 17·5, and 18·3 in the three preceding weeks, was 18·2 per 1000 during the week ending August 8th. During the past four weeks the death-rate has averaged 17 5 per 1000, the rates during the same period being 13·1 in London and 14 3 in Edinburgh. The 132 deaths of persons belonging to Dublin registered during the week under notice were one less than in the preceding week and included eight which were referred to the principal infectious diseases, against six, nine, and five in the three preceding weeks; of these, five resulted from diarrhœa and one each from small-pox, measles, and whooping-cough, but not one from scarlet fever, diphtheria, or "fever." These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates from the principal infectious diseases last week being 1·7 in London and 1·3 in Edinburgh. The fatal cases of diarrhœa, which had been one, one, and four in the three preceding weeks, increased to five last week. The 132 deaths in Dublin last week included 32 of children under one year of age and 30 of persons aged 60 years and upwards; the deaths of infants showed a decline of eight, and those of elderly persons an excess of 10, as compared with the respective numbers recorded in the preceding week. Six inquest cases and five deaths from violence were registered and 49, or more than a third, of the deaths occurred in public institutions. The causes of seven, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JULY, 1903.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JULY, 1903.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1903	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes	Death rate per 1000 living.	Deaths of Infants under one year to 1000 births.
		Small pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small pox.	Measles	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living

* Including membranous croup.

appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·4 per 1000 of the population, estimated at 4,613,812 persons in the middle of the year. In each of the two preceding months the rate had been 6·0 per 1000. The rates were considerably below the average in Hammersmith, Chelsea, Hampstead, Stoke Newington, Southwark, and Camberwell, while they showed the largest excess in Hackney, the City of London, Bethnal Green, Poplar, Bermondsey, and Deptford. The prevalence of small-pox during July showed but little variation from that recorded in the preceding month; of the 55 cases notified last month, 20 belonged to the City of Westminster, ten to St. Pancras, seven to Wandsworth, five to Lambeth, five to Camberwell, and three to Islington. The Metropolitan Asylums hospitals contained 66 small-pox patients at the end of last month, against 47, 60, and 57 at the end of the three preceding months; the weekly admissions averaged 15, against 12, 13, and 12 in the three preceding months. Scarlet fever was slightly more prevalent last month than it had been during June; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Paddington, Holborn, Finsbury, Bethnal Green, Poplar, Deptford, and Woolwich. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1685, 1738, and 1614 at the end of the three preceding months, had risen again to 1697 at the end of last month; the weekly admissions averaged 236, against 201, 226, and 195 in the three preceding months. The prevalence of diphtheria was considerably in excess of that recorded in the preceding month; this disease was proportionally most prevalent in Hackney, the City of London, Poplar, Bermondsey, Deptford, and Lewisham. There were 840 cases of diphtheria under treatment in the Metropolitan Asylums hospitals at the end of last month, against 760, 808, and 781 at the end of the three preceding months; the weekly admissions averaged 130, against 105, 120, and 119 in the three preceding months. The prevalence of enteric fever showed a further increase upon that recorded in recent months; the greatest proportional prevalence of this disease occurred in Fulham, Hackney, the City of London, Shoreditch, Poplar, and Battersea. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 53, 51, and 88 at the end of the three preceding months, had further risen to 119 at the end of last month; the weekly admissions averaged 18, against five, ten, and 17 in the three preceding months. Erysipelas was proportionally most prevalent in Kensington, Hackney, Holborn, Shoreditch, Bethnal Green, Poplar, Bermondsey, and Deptford. The 17 cases of puerperal fever notified during the month included two each in Islington, Hackney, Finsbury, Southwark, and Woolwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the various boroughs in which the deceased persons had previously resided. During the four weeks ending August 1st the deaths of 4424 persons belonging to London were registered; these deaths were equal to an annual rate of 12·5 per 1000, against 15·8, 14·2, and 12·9 per 1000 respectively in the three preceding months. The lowest death-rates in London last month were 7·0 in Stoke Newington, 7·2 in Hampstead, 9·3 in Lewisham, 9·4 in Wandsworth, 10·5 in Hackney, 10·7 in Camberwell, and 10·8 in Paddington; the highest death-rates were 14·5 in Southwark, 15·7 in Stepney, 16·2 in Bermondsey, 16·7 in Bethnal Green, 18·3 in Finsbury, and 18·9 in Shoreditch. The 4424 deaths from all causes included 510 which were referred to the principal infectious diseases; of these, 112 resulted from measles, 34 from scarlet fever, 48 from diphtheria, 85 from whooping-cough, 22 from enteric fever, and 209 from diarrhœa, but not one from small-pox, from typhus fever, or from any ill-defined form of continued fever. The lowest death-rates last month from these infectious diseases were recorded in Paddington, Chelsea, Hampstead, Holborn, Lewisham, and Woolwich; and the highest rates in Fulham, Finsbury, Shoreditch, Bethnal Green, Stepney, Bermondsey, and Deptford. The 112 deaths from measles were 88 below the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in the City of Westminster, St. Pancras, Finsbury, Shoreditch, Bethnal Green, and Battersea. The 34 fatal cases of scarlet fever showed a decline of 29 from the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in St. Marylebone, Bermondsey, Deptford, Greenwich, and Lewisham. The 48 deaths from diphtheria were less than one-third of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, Poplar, Bermondsey, Wandsworth, and Deptford. The 85 fatal cases of whooping-cough showed a decline of 73 from the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in Hackney, Finsbury, Bethnal Green, Stepney, Battersea, and Greenwich. The 22 deaths referred to "fever" were 15 below the corrected average number; of these 22 deaths, three belonged to Islington, three to Hackney, two to Fulham, two to Poplar, and two to Camberwell. The 209 fatal cases of diarrhœa were over 500 fewer than the average; among the various metropolitan boroughs the highest death-rates from diarrhœa were recorded in Hammersmith, Fulham, Shoreditch, Bethnal Green, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was nearly 61 per cent. below the average.

Infant mortality in London during July, measured by the proportion of deaths among children under one year of age to registered births, was equal to 103 per 1000. The lowest rates of infant mortality were recorded in Hampstead, Holborn, Battersea, Wandsworth, Lewisham, and Woolwich, and the highest rates in the City of Westminster, Shoreditch, Bethnal Green, Stepney, Bermondsey, and Deptford.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

THE temporary rank of Captain in the Army granted to temporary Lieutenant M. Taylor is dated July 2nd, 1902.

Captain C. T. Samman joins at Woolwich for temporary duty. Captain H. V. Prynne is ordered to join at Woolwich for duty. Captain F. J. C. Heffernan proceeds to London for a course of study at the Royal Army Medical College. Lieutenant-Colonel H. J. McLaughlin, D.S.O., retired pay, has arrived at York for duty as Recruiting Medical Officer at Bradford.

IMPERIAL YEOMANRY.

Scottish Horse: William Stewart Gray Kidd, late Surgeon-Captain, 1st Scottish Horse, to be Captain. Dated March 30th, 1903. Surgeon-Captain John Anderson, from 5th (Perthshire Highland) Volunteer Battalion the Black Watch (Royal Highlanders), to be Lieutenant. Dated March 30th, 1903. James Anderson Taylor to be Surgeon-Lieutenant. Dated March 30th, 1903.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Northumberland: Surgeon-Lieutenant R. A. Nesham to be Surgeon-Captain. Dated August 8th, 1903.

Rifle: 1st Volunteer Battalion the King's Own (Royal Lancaster Regiment): Surgeon-Lieutenant R. J. Morris to be Surgeon-Captain. Dated August 8th, 1903. 4th Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant R. Fielding-Ould to be Surgeon-Captain. Dated August 8th, 1903. 1st Volunteer Battalion the Dorsetshire Regiment: Surgeon-Captain W. G. Brett resigns his commission. Dated August 8th, 1903.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Glasgow Companies: The undermentioned Captains to be Majors: J. McGregor Robertson (dated August 8th, 1903) and A. Moyes (dated August 8th, 1903).

VOLUNTEER OFFICERS' DECORATION.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force:—*North-Eastern District: Artillery:* 1st Newcastle-upon-Tyne Royal Garrison Artillery (Volunteers): Surgeon-Lieutenant-Colonel Arthur Taylor Wear. *Rifle:* 2nd Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): Surgeon-Major William Sandham Symes and Surgeon-Captain William Moxon. 1st (Hallamshire) Volunteer Battalion the York and Lancaster Regiment: Surgeon-Lieutenant-Colonel John Wise Martin. *North-Western*

District Rifle 2nd Volunteer Battalion the Lancashire Fusiliers Surgeon Major William Pooley

THE ROYAL ARMY MEDICAL CORPS EXAMINATION

The entry for the Royal Army Medical Corps at the late examination has been a singularly good one, 72 men having applied in the first instance to compete for 30 vacancies, as has already been announced in THE LANCET Among the competitors were many men who had distinguished themselves at their respective medical schools, Guy s Hospital bearing off the palm with five men out of the first ten of the successful candidates The names are as follows —A O H Gray, M B Lond , D P Watson, M A , M B , D P H Cantab , I S Dudding, C H Robertson, M B Lond , F M M Ommaney, J S Powell, R H MacNicol, M B , B Ch Dub , O Levers M B Lond , D D Paton M B B Ch Edin , S L Pallant, O R Bradley, H H J Fawcett, B A Cantab , T J Wright, G A Kempthorne B A Cantab , J S MacEntire M A., M B , B Ch Dub , S E Lewis M B , B Ch Glasg , N D E Harvey, M B R.U I , J A Longley, M B , B Ch Vict , N S Dunkerton, P J Hanafin, D P H Irel , A O Osburn , M O Wetherell, M B , B S Durh , R T Collins , W MacD MacDowall, F J Turner, H O Hildreth F R.C S Edin , G S Mackay, M B B Ch Edin , J D Richmond, M B , B Ch Glasg , F M G Tulloch , and E M Glanvill, M B , B Ch Edin It is to be hoped that this service is at last attracting the attention it deserves and that the prospects of professional advancement which it now offers may prove a continued attraction to a thoroughly good class of young medical men in the future as in the present instance

INDIAN MEDICAL SERVICE EXAMINATION

The following is a list of the candidates for His Majesty s *Indian Medical Service who were successful at the competitive* examination held in London on August 3rd 1903 and following days Forty one candidates, of whom 23 had University degrees, competed for 16 appointments , 29 were reported qualified —

THE TREATMENT OF GOITRE BY DISTILLED OR RAIN WATER

To the Editors of THE LANCET

SIRS,—In the paper of which I made mention in my last letter I have collected nearly all the known facts about the production of goitre and a short *resume* may be useful in connexion with Dr C A Rayne s letter in THE LANCET of August 8th, p 424 The goitrous poison is born of the soil and the soil only It is absent from rain water Pliny says "Tales sunt aquæ quales terræ per quas fluunt. St Lager relates that the youths of a certain town hip in France in order to escape military service drank copiously for several months before the arrival of the recruiting authorities from a well the waters of which were notoriously goitrigenous Their thyroid glands rapidly enlarged and by this means they escaped service Lombroso relates a similar instance occurring in Lombardy where the formation of goitre was even more rapid "La fonte del gozzo ove sogliono andare i giovani all' epoca della coscrizione onde acquistare *in quindici giorni* quel difetto che li sottrae dal servizio '

The hardness or otherwise of a water has nothing to do with its goitre producing faculties Some of the softest waters are the most goitrigenous One poisonous water I am acquainted with contains only 0 5 of a grain per gallon of calcium carbonate No calcium or magnesium salts in water cause goitre nor does the absence of chloride of sodium (a reputed cure) The two theories most in vogue at present are (1) the bacillary theory of the Italian physicians Lustig and Carle and (2) what I may call the metallic salts theory advocated by St Lager in his two series of ' Études sur les Causes du Crétinisme et du Goitre Endémique ' and the salts which he chiefly makes reference to are the sulphides of iron and copper (iron and copper pyrites) I have not time to go into the *pros* and *cons* of these two theories I shall content myself with saying that the iron theory has much to be said in its favour The flushing action of an iron containing water on a loosely connected gland like the thyroid must be considerable I have found evidence of iron in many goitrigenous waters, but not invariably, nor is it likely to be present in every sample of water examined In proof of this iron theory it is a curious fact that in very numerous instances the water coming in contact with pyritous marls is highly goitrigenous In England the blue marls of the Gault and Wealden undoubtedly produce goitrigenous water In France the marls corresponding to the above the ' marnes aptiennes ' and the "marnes neocomiennes inférieures, are equally dangerous Both these formations in France contain a superabundance of iron bisulphide and the blue colour of the English marls is of course due to disseminated iron pyrites. Goitre is found sometimes on the chalk and chalk marl in England We know that calcium carbonate does not produce goitre What then is the cause of the disease in this case? So far as I am aware the only accidental minerals found in these formations are disseminated lime phosphate glauconite (a hydrous silicate of iron and magnesia) and curiously enough marcasite which is a very readily decomposable form of iron bisulphide I could quote numerous instances of the same kind in support of this theory It may be that some subtle combination of organic matter with the decomposing sulphides may be the true cause of goitre but much work remains still to be done on this question Dr Rayne will find a mine of information on endemic goitre in the works of St Lager which, I think, are among the ablest ever penned by a physician Herein, too, are related many instances of goitres cured by the imbibition of rain water, showing that Dr Rayne s idea that this was a new method of treatment is not founded on fact, as it has happened in numerous instances in the history of medicine and is now a matter of fairly ancient knowledge. Apologising for the length of this letter,

I am, Sirs, yours faithfully,

LOUIS E STEVENSON M B B C Cantab , F G S

Temple Sowerby Penrith August 9th 1903

MEDICAL DOCTRINES OF HEREDITY

To the Editors of THE LANCET

SIRS,—It is interesting and instructive to find the traditional conflict between the advocates of vitalism and naturalism making its periodical appearance , interesting also perhaps to see the vitalist school relinquish none of its ancient ardour or infallibility, and certainly interesting, in particular to discover no allusion to Professor Weismann by those who so strenuously support his views. This omission on the part of Dr G Archdall Reid and Dr C R Niven is unkind to say the least of it I confess that I cannot quite understand however, why this discussion has been reopened, for neither Dr Reid nor Dr Niven, in the course of reasoning which leaves the impression of being more subtle than lucid, seems to have advanced anything particularly new When I took up THE LANCET this morning and found that a correspondence was being carried on in its columns on the medical doctrines of heredity I thought that I would at least come across some reference to Professor Kassowitz's recent contributions to this subject. I was all the more justified in this expectation as the contributions in question, it would appear, are of a very striking nature. As far as I can understand from mere hearsay Professor Kassowitz denies both the struggle for existence and natural selection. He looks with suspicion on the latter theory as merely the argument for design in its modern disguise, as the latest phase of teleology, or as a substitute for providential supervision. Natural selection, indeed, may be regarded as the scientific conception of the agency by which the wicked are entirely swept away and the good are rewarded—just as Dr. Reid and Dr. Niven would have it. I may say *en passant* that my first impression on hearing of Professor Kassowitz's views was one of disconfidence ; it struck me that an attempt was being made to invalidate the authority of Darwinism in order to throw discredit on the Nietzschian adoration of strength and its praise of hero-worship. And I still would think it difficult for a Jewish writer, even on biological or sociological subjects, to refrain from indirectly protesting, like Max Nordau, against Nietzsche's treatment of the Jewish character as a factor in religious and social evolution.

But to return to my subject and Dr. Niven. This writer demands from "Dr. Wiglesworth, or any other, one indisputable instance of the transmission of an acquired trait ...... in multicellular organisms." Not long ago this challenge would have been issued without reservation of any description. Such was the case when Professor J. G. Adami pointed out how Ehrlich's side-chain theory might throw some light on question of heredity. I remember at the time referring to the remarkable experiments in the laboratory of the Naples Aquarium where it had been proved that the distinction between the germ plasm and the somatic plasm in unicellular organisms had not the absolute character claimed for it by Professor Weismann and his school. These investigations were so significant that there need be no hesitation to-day in making some concession to the dualistic prejudices shared by Dr. Niven.

I presume from Dr. Niven's position that he has not seen the note which I published about the same time in the *British Medical Journal* concerning the transmission of acquired characters in dogs. The evidence which I was able to bring forward was, I fancy I am justified in saying, of a very convincing kind. It referred to some observations made at Nice by Dr. Frémont on the consequences of his method of isolating the stomach in dogs. Dr. Frémont could not understand the objections made by Weismannism to the Darwinian theory of the transmission of acquired characters. "I have unfortunately," he remarked, "only too ample reason to feel the truth of Darwin's views. The puppies of the sheep-dogs from which I obtain my supply of gasterine already show a contracted stomach secreting a much smaller quantity of gastric juice than the parents and an enlarged intestine which bulges into the incision I make in my operation. The second generation of my '*opérés*' are useless for any purpose connected with the preparation of gasterine." I added to my note that these statements of my friend were absolutely unprejudiced, because Dr. Frémont had never looked upon the objections of the newer school of evolutionists as sufficiently cogent to attract his attention.

I am, Sirs, yours faithfully,
A. W. GILCHRIST, M.D. Paris.

La Bourboule, July 27th, 1903

To the Editors of THE LANCET.

SIRS,—I am exceedingly sorry that I was unable to reply to Dr. Wiglesworth's letter in THE LANCET of August 1st. As I was out of Great Britain I was not even aware that my own letter had appeared in your columns, nor did I see Dr. Wiglesworth's reply till my return home.

In the beginning, however, let me disclaim any desire or intention of trying to take care of Dr. Reid. No one who has carefully tried to master the teaching of "The Present Evolution of Man" would ever dream of trying to shield Dr. Reid from the attacks of anyone, either inside or outside our profession. As Dr. Wiglesworth correctly observes, Dr. Reid is well able, and I would go farther and say more than able, to take care of himself, and that especially so from anyone who advances arguments like those of Dr. Wiglesworth.

Dr. Wiglesworth contends that I have misconstrued his position. Very well. Put as simply as possible Dr. Wiglesworth believes, and claims that he has proved by his statistics, that parental drinking leads to increased desire for alcohol as well as to increased mental instability in the offspring. That I, as well as those belonging to the newer Darwinian school, deny. Surely that is plain and admits of no misconstruction. It is not denied that the offspring developed from germ cells may be influenced in this or that possible or probable direction by injurious agents—for example, alcohol—circulating in the parents' blood. What is denied is that the changes produced in the offspring are the same as those produced in the parent "except as a coincidence so rare that it may be neglected as a factor in evolution." For example, suppose a man acquires a taste for tomatoes, it is not denied that the eating of tomatoes may influence his germ cells in some possible or probable direction, but it is denied that the offspring arising from these germ cells will have a greater desire for tomatoes than otherwise would have been the case. But more, suppose a man contracts scarlet fever, for instance, and recovers, that is acquires immunity against it, it is not denied that his germ cells are uninfluenced by the toxin circulating in his blood. What is denied, supposing he afterwards becomes a father, is that the child or children developed from these germ cells will have a greater natural resistance to scarlet fever than otherwise would have been the case. The evolution of our race with regard to this special disease has proceeded and is proceeding along lines of an inborn capacity for acquiring immunity against it. Some take the disease severely and die ; others take it slightly and recover ; while others seem to be totally immune. Those who have not varied favourably tend to be eliminated, leaving the continuance of the race to those who have so varied, that is, who have an inborn immunity or an inborn power of acquiring immunity against the disease. The same is to be said with regard to every other infectious disease With regard to alcohol or any other poison the same reasoning is to be employed. Suppose a man becomes addicted to alcohol it is not denied that his germs may be influenced in some possible direction. What is denied is that the offspring derived from these germs will have a greater desire for alcohol than they otherwise would have had. If this were so then they would make a different start in life from the parent, because to the child's inborn capacity to enjoy alcohol would have to be added the increase of capacity due to the parents' drinking, and this increased capacity accumulating generation after generation would at last lead to such drunkenness as to result in the extermination of the race. However it has come about, there has arisen in man during his evolution a desire for, or capacity to enjoy, alcohol. The very earliest records tell of man's drinking. There is no nation now sober which was not at one time very drunken. Nor is there one race which never had any acquaintance with alcohol till recent times that is not now drunken. If parental drinking led to increased filial drinking or filial insanity, and as these would increase generation after generation, we would expect that those races which have had the most prolonged acquaintance with alcohol would be the most drunken and would have a bigger death-rate from alcohol than those that have not had this prolonged acquaintance with it. The exact opposite, however, is the case. Did parental drinking lead to filial insanity the same result would ensue—that is, extermination of the race. In the case of alcohol, as in that of scarlet fever, natural selection has been at work eliminating the unfit and leaving the continuance of the race to those who have varied favourably—that is, in the inborn power of tolerating alcohol, or avoiding it, or both. Now it must be insisted upon, in spite of the iteration and reiteration of Dr. Wiglesworth, that no one has said "that the germ plasm is incapable of receiving permanent injury by the agency of poisons circulating in the blood—that is, of course, that the damage to the individual germ cells is never of such a nature as to lead to permanent alteration in the organism which results therefrom."

Dr. Wiglesworth is quite right when he goes on to say, "Either a modification can be produced in the somatic cells of a child as a result of such influence or it cannot. If as a result of the development of germ cells in a vitiated nutrient medium the child resulting therefrom is modified in any direction, however slight, then a definite germinal variation has been produced by the agency of the poison in question." But possibly and probably Dr. Wiglesworth is altogether wrong when he goes on to say further that if the neo-Darwinism contention is correct it may be a "matter of indifference as regards the welfare of such offspring whether the germ cells from which they arise are developed in a vitiated nutrient medium or the reverse" We at present know too little about heredity to say it is or is not a matter of indifference whether the germ cells are developed in a vitiated nutrient medium or not. *However, with regard to permanent alterations* being produced in germ cells and the resulting offspring from poisons, &c, circulating in the blood, this is probably correct For since the child varies somewhat from the parent the germ cell from which he is derived must also have varied somewhat from the germ cell from which the parent was derived and it seems probable (neglecting the effects of conjugation) that this could only have arisen from some external cause—for example, alcohol circulating in the blood What is denied is that such changes in the blood usually produce changes of such a kind in the germ cell as result in variations in the offspring derived from these germ cells similar to those produced in the parent organism. For example, suppose a bicyclist develops his calf muscles to a great extent this modification may so alter the blood or nutrient parts of it as to cause an alteration in the germ cell which will, therefore, cause it to develop into an organism different from that which would otherwise have been the case It is, however, difficult to conceive that this variation in the offspring will be of the same kind as that in the parent In other words, it is difficult to believe that because the parent developed his calf muscles the child will have better calf muscles than he otherwise would have had If this ever does happen—that is, if ever an acquired trait is transmitted—it must be so rare that no indisputable instance of it has yet been recorded and thus as a factor in evolution may be neglected

I pointed out in my last letter that the accumulation and transmission of acquired traits is probably the normal condition of things in low unicellular organisms, as witness the conversion of small-pox into vaccinia by passing the virus through the cow, but that such obtains in multicellular organisms, notwithstanding Dr Wiglesworth's statistics, there has not yet been any evidence advanced worth the time spent in its examination

I am more than sorry if I have misread any part of Dr Wiglesworth s first letter In that letter he evidently insists that the actions of poisons, &c, on the germs (apart from conjugation) will cause the offspring developed from these germs to vary in certain *definite* directions To that end his statistics are supposed to prove that parental drinking will cause filial intemperance or filial mental instability The foregoing part of this letter and my last letter prove that for this contention there is not one iota of justification Were this so then we would expect every member of a litter of pups or kittens to resemble exactly one another, for the germs have been subjected to the same conditions of environment We know, however, that no two members of the same litter correspond in any one character or trait.

Dr Wiglesworth next refers to the 'Mohammedan races which show us millions of human beings who are perfectly sober not by virtue of such an evolution but in consequence of the operation of religious sanctions" Granted But though the past history of these races is well known the future has yet to be written It must also be remembered that this craving for alcohol is not the only desire of man that has been counteracted by his religious systems Millions and millions of men and women have denied themselves *the perfectly natural gratification of sexual love* because of their religious systems, and though their sexual instinct was counteracted it was never abolished Similarly, though the desire for alcohol has been counteracted it never has been abolished Let those races change their religion (they have done it before and may do so again) to one like the Christian religion which does not demand total abstinence, and it may be the last state of those races will be worse than the first. Again if these races are Mohammedans and abstainers we must take into consideration the price they are paying in knowledge, belief art, morals, law, customs, &c.—that is, in culture or civilisation

I need not follow Dr. Wiglesworth further, for any other question he raises has been answered in the preceding part of this letter or in my previous one In his last sentence, however, he asks, "Can Dr Reid or Dr Niven furnish evidence to show that on the average the children of alcoholic parentage are as stable and healthy as those of parents not so circumstanced? I respectfully decline to do any such a thing Dr Wiglesworth has asserted that parental drinking causes filial intemperance and filial insanity These statements have, I trust, been shown to be wrong It is for Dr Wiglesworth to prove *his* statements It is no part of my business to prove an exact opposite I may say, however, that it would be perfectly easy to give the proof he asks, but the disproof of his assertions is the beginning and end of my task.

I am, Sirs, yours faithfully,

Liverpool August 7th 1902. C R. NIVEN

A MINISTRY OF HEALTH

To the Editors of THE LANCET

SIRS,—In reference to a paper which I had the honour of reading in the Section of State Medicine of the seventy first meeting of the British Medical Association on July 31st at Swansea on the formation of a Health Ministry I am invited to reply to the following points raised by distinguished members of our profession —

1 That friction would be caused between the proposed Minister and the Local Government Office and a deadlock in public health affairs ensue
2 That local administration of sanitary matters would become detached from other departments of local government
3 That the first step towards a proper State sanitary service would be the improvement in status and pay of the medical department of the Local Government Board

I think that the first two points may be answered together, A Minister of Education has recently been appointed, with obvious advantage, at a time, curiously enough, when local educational and general government has been in process of unification Thus it is clear that the Ministry of Education can coöperate harmoniously with the Local Government Office though local administration of duties is combined In Belgium and Canada, in the United States of America, in Germany in Sweden, and in Denmark the State public health administration is incorporated in departments of agriculture navy, police, and education, a "medical council," and the Ministry of Justice respectively [1] The national administration of public health services is, therefore, not confined to central offices of local government in other countries These facts strengthen the supposition, to my mind, that discord need not arise by a separation of the medical department of the Local Government Board to form the nucleus of a Health Ministry

As regards the third point, the improvement in status and pay and numbers of the medical department of the Local Government Board is clearly essential to the promotion of a proper State sanitary service Would this not be one of the many matters to receive the attention of the proposed Ministry of Health?

The support of the medical profession appears to be a *sine qua non* to the formation of such a central medical department and it is hoped that these questions when raised will receive their close attention

I am Sirs, yours faithfully,

Plymouth August 8th, 1903. F G BUSHNELL

TRIFID STOMACH

To the Editors of THE LANCET

SIRS,—In THE LANCET of August 8th, p 415, appeared an annotation on hour glass stomach in which, referring to an interesting case of trilocular stomach reported in the same issue (p 388) you state "It is, we believe, the first case of trifid stomach on which an operation has been performed" May I draw your attention to a paper which I read before the American Surgical Society on May 8th, 1901 and published in THE LANCET of May 25th, 1901, p 1458 Here I described a case (Case 22) of trifid stomach under the name of double hour glass contraction of the stomach on which I performed gastroplasty and gastrolysis and cured the patient who remains well This case preceded the one you describe as the first by more than four years and although one of the strictures was produced by adhesions and the other by cicatricial contraction the stomach was divided into three distinct cavities The case is referred to and briefly described in the work "Diseases of

---

[1] See also the Case for a Ministry of Health p 160 et seq by F Scott F C A citing Palmberg and Newsholme s Public Health and its Applications.

Holden, the architect appointed by the trustees after the disaster—what a pity he was not appointed before—five houses in a row belonged to the same owners, two of which did not collapse. The outside walls were nine inches and the inside walls were four and a half inches thick, "the ordinary cottage construction." In his opinion the collapse was caused by "the giving way of the chimney" between two of the houses. He did not think there was anything suggesting that blame attached to anyone. "The property, like hundreds of other houses in Manchester, was old and of a poor class." Mr. Price, the architect for the corporation, suggesting that if the property had been examined by an architect its dangerous condition might have been discovered, elicited the statement by Mr. Holden that he had never received such instructions during his more than 40 years' practice. He said also in answer to a juryman that "in property of this construction a falling chimney would be bound to bring other houses down." The city architect indorsed Mr. Holden's views and said that "the dangerous building staff" of the corporation consisted of one man. He said he thought that the corporation was responsible only when the property was dangerous to passengers in the streets. "Not to the tenant?" "No. The corporation had no right to enter a house and could only examine it from the outside." Mr. Price said that he was thinking of suggesting to the corporation the reorganisation of all the work of the building department, of which he had only had charge for 12 months. The whole of the evidence in this case suggests the idea that a great deal of the old and poor property in Manchester is in a condition dangerous to the occupants, and that in some way or other the owners or the corporation or both should exercise closer supervision. One inspector for this kind of property cannot see to the condition of the houses in all the "mean" and other streets of Manchester. The coroner thought that the jury would be warranted in finding that there was negligence in the management of the property, "culpable, if they liked, but not necessarily criminal." To constitute the latter "they must be satisfied that the accident was the direct and not a remote result of that negligence." After deliberating in private the jury found "that the children died from suffocation caused by the collapse of the buildings" and that there were criminal neglect on the part of the agent and culpable neglect on the part of the corporation inspector. This was really a verdict of manslaughter against the agent who appeared at the city police-court in the afternoon charged with manslaughter and was remanded on bail. It seems as if the individual were to suffer for the faults of the system. The above story is calculated to make property owners, and especially the owners of the squalid dwellings too common in the poor districts of our towns, and our corporate authorities more alive than they have been to their own duties and responsibilities.

The New Infirmary and Medical Education.

On July 31st the ceremony of conferring degrees of the Victoria University took place in the Whitworth Hall. All the degrees were those of Bachelor of Medicine and Bachelor of Surgery, with one exception, the conferring of the Master of Arts degree on a lady from University College, Liverpool. In the absence of Lord Spencer, the Vice-Chancellor, Dr. Alfred Hopkinson, LL.D., Principal of Owens College, opened the proceedings and in the course of his remarks spoke of the new infirmary which is so soon to be built near Owens College and of the influence which its greater proximity will exercise on medical education. He said that it was impossible not to take the opportunity of expressing the satisfaction of those interested in medical education at the prospect "of a new infirmary being very shortly erected with adequate facilities for clinical study, and that owing to these increased facilities, the proximity of the new infirmary to the College, and the hearty coöperation of the governing bodies, both lay and professional, of the two institutions there will soon be advantages offered for medical study in Manchester second to none in any part of the country." He recognised the fact that medical education, although based on broad and thorough scientific preparation, must be of a completely practical character, and that it is probably impossible to overrate the importance of the clinical side of it. He hoped that the coöperation of those engaged in imparting and increasing scientific knowledge and of those daily engaged in practice would result in further additions being made to our knowledge of medical science and art.

August 11th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The University of Liverpool.

THE first meeting of the Council of the new University of Liverpool was held in the Senate room at University College, on August 4th, the Chancellor, the Earl of Derby, K.G., presiding. The Chancellor laid upon the table the Charter of the University and said that the occasion that had brought them together—the first meeting of the new University Council—was one of great importance. The work that lay before them would demand all the resources of their wisdom and strength, and while they must act boldly and hopefully they must at the same time act prudently and cautiously. They must resolve that they would exercise due forethought in carrying out the work which they had been appointed to undertake and must insure that everything should be done thoroughly and efficiently. They had the satisfaction of knowing that throughout the course of the University movement they had been cordially supported by the goodwill of their fellow citizens and that in parting from their colleagues in the Victoria University they had parted on the most friendly terms. For himself he fully recognised the honour that had been conferred upon him, by the nomination of his Sovereign, as the first Chancellor of the new University, and he pledged himself to the utmost of his power to help to lay the foundations of a university in which the studies of arts, science, and other subjects should receive all possible expansion, and should be so organised as to earn for the University the position of power and privilege now conferred upon it. Mr. E. K. Muspratt was appointed president and Mr. J. W. Alsop vice-president of the University Council and a committee was elected to draft ordinances and regulations as required by the statutes. It was also agreed that an inaugural ceremony should be held in St. George's Hall on some day in the autumn and a subcommittee was appointed to confer with the Lord Mayor and to arrange details of the ceremony.

Woolton Convalescent Institution.

At the twenty-ninth annual meeting of the supporters of the Woolton Convalescent Institution held in the Gladstone Hall of the institution under the presidency of the Lord Mayor, who was accompanied by the Lady Mayoress, the Lord Bishop of the diocese, Sir William Tate, Bart., and others, the secretary submitted the annual report, in which the council recorded with pleasure another satisfactory year of progress and work in the institution. The number of patients was steadily maintained, the figures for the year being 2736; the contributions received showed a further increase in annual subscriptions, which reached £1045, both figures being the largest on record. The liberal grant to subscribers of free and partly paid admission forms inaugurated some years ago is undoubtedly an influence which has helped the success and prosperity of the institution. The death of Mr. William Rathbone caused a vacancy in the office of vice-president. In response to the unanimous request of his colleagues on the council Sir William Tate, accepted the position and also continued the duties of treasurer. He resigned the chairmanship of the council, to which Mr. William Oulton, C.C., was unanimously elected. Sincere thanks were accorded to all subscribers and donors and also for the special donations. The legacies received during the year had been large and were as follows: from the executors of the late Mr. Henry Tate, formerly of Allerton, £1000; from those of the late Mr. James Barrow, £250; and from those of the late Mrs. Charles Turner, £200. The greater part of these legacies have been invested and a balance has been retained in order, if thought desirable after due consideration, to carry out a long contemplated improvement in the grounds of the institution. It was proposed to lay out the land in front of the building by making walks and flower-beds and planting shrubs and trees, and so giving additional attraction by beautifying and utilising more fully the extensive grounds; this was a matter of great importance in a convalescent home as an inducement to patients to remain as much as possible in the open air, a most valuable adjunct to treatment. Since the close of the year the committee of the Liverpool Transvaal War Equipment Fund had, through the Lord Mayor, contributed £500 for the endowment of a bed to be called "the Transvaal War Equipment Fund Bed" and to be used for the benefit of sufferers through the war or other local deserving cases, thus showing in a practical way the appreciation of the efforts to render service to the soldiers invalided in 1900. The financial statement showed that the total receipts were £5926, and that a balance had been reserved for improvements to the pleasure grounds (as referred to in the report) of £562 5*s.* 1*d.* There were now eight endowed beds and 14 free beds, among the latter being one supported by the West Derby board of guardians. The thanks of the subscribers were accorded to Dr. J. M. Chisholm, the visiting physician, and to the household and nursing staff.

August 11th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Bristol Health Report.

IN his report for 1902 the medical officer of health of the city of Bristol, Dr. D. S. Davies, deals at some length with the housing of the working classes. Though there are in Bristol no large concentrated slum districts lending themselves to a sweeping comprehensive scheme for clearing out an insanitary area there are still isolated groups of houses and courts which require to be dealt with. When reporting in the year 1896 upon the best means of providing houses for those persons who were turned out of dwellings which were condemned as uninhabitable, the medical officer of health and the city engineer deprecated the erection of block dwellings, flats, or similar buildings tending to crowd a large population upon a small area. The corporation, no doubt having this expression of opinion in mind, has recently erected in different parts of the city 60 tenements, 22 of two rooms and 38 of three rooms. The rent of the former is 3*s.* 3*d.* per week and that of the latter is 4*s.* 6*d.*, while the number of inmates is restricted to three and five respectively. These houses are built in rows and are two storeys high. There is one tenement on the ground floor and the other on the first floor, the latter being approached from an iron balcony, three feet wide, which runs the whole length of the building and which is reached by a wide open fireproof staircase in the centre of the row. There is a large open yard at the back of the houses and each tenement has a washhouse and a water-closet. The bedrooms contain about 1000 cubic feet of air-space and each one has a fireplace. A municipal lodging-house to accommodate 120 persons is also being erected in Bristol at a cost of about £7000. There are at present in the city 35 registered common lodging-houses with accommodation for 819 persons. When discussing the retention of underground bakehouses in connexion with Section 101 of the Factory and Workshops Act, 1901, Dr. Davies says that the only logical way of dealing with such premises would be forthwith to condemn every one at present existing, as the Act itself permits no new one. In considering which of the 51 underground bakehouses should be retained the corporation has, however, decided to adopt suggestions which very closely follow those agreed upon by the Incorporated Society of Medical Officers of Health.

Action for Damages against the Hereford Corporation.

In view of the possibility of "return" cases of infectious disease many sanitary authorities which possess isolation hospitals are now in the habit of discharging patients only on the understanding that no responsibility attaches to the authority in the event of other cases of the disease occurring among members of the patient's household. The necessity for taking this precaution has been emphasised by the recent verdict of a Hereford county-court jury which awarded £30 damages to the father of a child said to have been negligently discharged from the corporation fever hospital whereby several other children contracted scarlet fever. The circumstances of the case differed somewhat from others in which damages have been paid by sanitary authorities. The patient in question, who remained in hospital for eight weeks, was attended throughout the illness and was discharged, not by the medical superintendent of the hospital but by a private practitioner. On the day of discharge the child was given a bath, the clothes were disinfected, and the child then returned for about ten minutes to the matron's room, which communicates with the hospital proper by a corridor. It was contended that during this period the patient became re-infected and upon returning home infected other children. The county-court judge in directing the jury laid great emphasis on the absence of a discharging block at the hospital and the non-provision of this accommodation evidently influenced the jury in its verdict.

The Meeting of the British Medical Association.

The camp which was organised at Swansea during the meeting of the British Medical Association was so pronounced a success that this method of supplementing hotel accommodation will no doubt be a feature of future meetings. At the Mumbles where the Swansea camp was situated the 20 bell tents and a mess tent were pitched in an inclosed two-acre field having a southern slope. Within 100 yards was Limeslade Bay, a tiny cove with a sandy bottom where bathing could be indulged in. There was no water-supply on the site of the encampment but sufficient for all requirements was brought in carts from a distance of one and a half miles. The general comfort of the campers was looked after by two camp orderlies from the 3rd Glamorgan Rifle Volunteers and the catering was undertaken from one of the Swansea hotels.

The Cossham Memorial Hospital.

The first meeting of the trustees of the scheme sanctioned by the Court of Chancery for the administration of the Cossham Memorial Hospital [illegible] the presidency of the Lord [illegible] approved of for the erection of [illegible] near Bristol. The institution [illegible] for 44 patients and will be surrounded by about four acres of land. The cost of building and furnishing is estimated at £23,300 and the remainder of the late Mr. Cossham's estate, which is about £80,000, is to form an endowment for the charity.

A Medico legal Cricket Match.

A cricket match was played at Cardiff on August 7th between a team of medical men and solicitors respectively and resulted in a draw very greatly in favour of the medical players.

August 11th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Chief Secretary and the Irish Medical Association.

THE conflict between the Local Government Board and the Irish Medical Association becomes more critical every week. Dr. L. Kidd of Enniskillen, President of the Association, has written to the Dublin papers in reference to the Chief Secretary's reply to a question by Mr. O'Brien, M.P., in which the former is reported to have said:—

> I think their claims would be more deserving of recognition if they abandoned such practices and awaited the report of the Viceregal Commission which is looking into the amalgamation of unions and other Poor-law matters.

And again:—

> They would be more likely to attain their object if, instead of pursuing these practices, they awaited the report of the Commission.

Dr. Kidd inquires whether the Chief Secretary has forgotten his answer to Dr. E. O. Thompson, M.P., on March 25th, when he stated:—

> [illegible] nother [illegible] highly [illegible] in the [illegible] a more economical administration of the [illegible]

Dr. Thompson himself also writes on August 1st and the following is an extract from his letter:—

> I have lying before me Mr. Wyndham's reply to a letter of mine distinctly refusing to enlarge the scope of inquiry of the Viceregal Commission so as to enable it to consider the grievances of the doctors.

He now proposes to ask the Chief Secretary to appoint a Royal Commission to report upon the amalgamation of unions and other Poor-law matters including the claims of the union medical officers of Ireland.

The Nursing Trouble at Granard.

Dr. Joseph Smyth, Local Government Board inspector,

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, AUGUST 6TH.

Typhus Fever in the East.

Mr. HERBERT ROBERTS asked the Secretary of State for India whether he had received any report from the medical officers attached to the Seistan-Nushki Railway survey party, or from Colonel MacMahon's Afghan Boundary Commission with reference to the appearance in their ranks of typhus fever or to the effect that several surveyors with one or other of these expeditions had perished from thirst in the Seistan deserts; and whether he could give any particulars as to the casualties which had taken place.—Lord GEORGE HAMILTON replied: I informed the hon. Member for North Manchester on July 30th that I had received no information as to the prevalence of typhus fever among the workers of the Quetta-Nushki Railway. As to the Seistan Irrigation and Boundary Commission it appears from Colonel MacMahon's reports that typhus fever is very prevalent in Seistan and that there was an outbreak in his camp early in May, six cases having occurred, of which five were fatal. Steps were at once taken for segregation and Colonel MacMahon reported on June 8th that his camp had a clean bill of health. On June 24th he reported the deaths of a native surveyor and three subordinates owing to the failure of their water-supply.

Adulterated Whisky.

Mr. KILBRIDE asked the Chancellor of the Exchequer whether he proposed to take any, and if so, what, steps with the view of securing the purity and maturity of alcoholic drinks; whether he had received any official reports showing that adulterated whisky was a cause of lunacy; and whether he would consider the advisability of setting up a standard of purity for spirits in the interest of public health.—Sir WILFRID LAWSON: Will the right hon. gentleman also say whether he has any official information showing the evils done by unadulterated whisky?—Mr. RITCHIE replied: I am afraid that the latter question is rather too large to be addressed across the floor of the House. With regard to the question by Mr. Kilbride the answer to the first two portions is in the negative. Of course, I shall be glad to consider any evidence or representations on the subject that may be laid before me.

Mr. MACVEAGH : on. gentleman whether he
has received any re in Glasgow on the subject
of lunacy following tch whisky?

No answer was given.

Trained Nurses and Nuns.

On the vote for the Local Government Board for Ireland, Mr. FARRELL said that owing to the action of the Local Government Board the nuns who had hitherto been the nurses in the Granard union hospital had had to retire and their place was now taken by lay nurses who were a considerable expense to the ratepayers. He did not object to the system of trained nurses, but he objected to the way in which the change had been carried out. Friction was brought about in the first place by the medical officer of the union who began to make adverse reports on the nuns. The latter bore with all the insults for four years, but in 1900 the position of affairs became intolerable. The inspector of the Local Government Board who was sent down in 1900 patched up a peace to which all parties agreed and the Local Government Board was largely to blame in the matter because it did not adhere to the arrangement made by that gentleman. In the end the Local Government Board, instead of deciding the personal issue, censuring those who ought to be censured, and laying down a course to be followed by the officials in future, sent an ultimatum to the board of guardians which it threatened to dissolve. The bishop, finding that there was no redress for the nuns, withdrew them from the institution and left the Local Government Board to find a way out of the difficulty.

Mr. WYNDHAM replied that no reflection whatever was cast upon the nuns. These ladies were doing excellent work in the union hospitals at great personal self-sacrifice and as their services were most acceptable to the patients it would be a great loss to the people of Ireland if they were to retire from the workhouses. But the nuns did not care to perform and, indeed, ought not to be asked to perform, some parts of hospital work and therefore it was essential that they should have the assistance of trained nurses. He had always expressed the view that the rates pressed heavily on the people of Ireland, but undoubtedly the desire for a higher standard of nursing now prevailed and, indeed, the guardians of the Granard union admitted its necessity. If therefore Dr. J. M. S. Kenny expressed regret for the manner in which he made some of his complaints with respect to the nuns why should not those ladies return to the Granard workhouse and bring to an end a lamentable state of things?

Mr. T. M. HEALY said that his sympathy was entirely with the ratepayers. Every fad of a medical man—the discovery of a new disease or a new cure—was certain to receive the support of the Irish Local Government Board. One did not read of these diseases and cures in Shakespeare or the Bible. The people of those days led as healthful lives as the people of to-day although they had no Local Government Board to look after them. If medical fads were to be carried out let it
of the local ratepayers but at the cost of the
small union hospital they must not expect all
might find in Guy's or St. Thomas's Hospital.
he drew from the whole matter was that there
should be some more representative people on the Local Government Board. The idea of making people happier and more comfortable was the last thing that entered into the minds of these gentlemen.

The matter then dropped.

FRIDAY, AUGUST 7TH.

The Motor-car Bill and Medical Men.

At the end of a 15 hours' sitting in connexion with the Motor-car Bill,

Mr. SCOTT MONTAGU moved the insertion of the following new clause, which explains itself: "A medical man driving a motor-car or cycle for the purpose of attending a patient who is in urgent need of his assistance shall not be liable to any penalties for exceeding the limit of speed provided under this Act."

Mr. LONG opposed the proposal on the ground that it was unnecessary. A medical man was always known in his district and no policeman would interfere with him.

Mr. SCOTT MONTAGU said that he knew of a case in which a medical man had been fined in such circumstances.

Major JAMESON appealed to the President of the Local Government Board to accept the amendment.

Mr. SCOTT MONTAGU said that he felt very strongly upon the point which, he mentioned, had been taken up by several of the medical journals. He could assure Mr. Long that the matter was not trivial

The proposed new clause was negatived without a division.

MONDAY, AUGUST 10TH.

The Case of Dr. McCarthy.

Dr. E. C. THOMPSON asked the Chief
of Ireland, whether he would explain
for Ireland had informed Dr. McCarth
the temporary appointment of medical officer of Tullamore Dispensary, that his conduct in resigning the appointment would be inquired into by a medical inspector and that if it was found that he had resigned without sufficient cause he would be prohibited in future from holding any Poor-law appointment; and whether he would state under what statute or by-law the Local Government Board had so acted.—Mr. WYNDHAM replied: Dr. McCarthy refused to enter upon the duties of the office to which he had been appointed with the approval of the Local Government Board. The Board thereupon requested the guardians to call upon him to take up his duties and stated that in the event of his still refusing to do so an inquiry would be held into the circumstances with a view to his removal from the office by sealed order. The authority for the Board's action in the case will be found in Sections 8 and 16 of the Poor Relief Act of 1851.

Salaries of Dispensary Medical Officers.

Dr. THOMPSON asked the Chief Secretary to the Lord Lieutenant of Ireland why the Local Government Board had refused in several instances recently to sanction an increase of salary granted to dispensary medical officers by boards of guardians.—Mr. WYNDHAM replied. Every application for an increase of salary receives the careful consideration of the Local Government Board and in any case in which the Board refuses to sanction an increase the reasons are fully communicated to the board of guardians concerned. If the honourable Member will give a reference to the particular case in which he is interested the reasons upon which the Board's decision was based will be ascertained.

Medical Officers with the Nigeria Force.

Mr. CHURCHILL asked the Secretary of State for the Colonies whether he would state how many medical officers and veterinary surgeons were serving with the Northern Nigeria Force during the month of June last.—Mr. CHAMBERLAIN replied: The establishment of the medical department in Northern Nigeria whose duties include attendance on both military and the civil officials, contains 27 medical officers, of whom, owing to the absence of the remainder on leave, about 18 are usually in
the Protectorate. The Kano-Sokoto expe
broken up in March and the small body of
in the field has been engaged in the pursui
I have no information as to the number of
surgeons attached to this small force.

TUESDAY, AUGUST 11TH.

Medical Consultations in Ireland.

Dr. THOMPSON asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware of a circular issued from the office of the Inspector-General of the Royal Irish Constabulary, dated July 20th, 1903, which forbids the medical attendants of the Royal Irish Constabulary calling in consultation any other medical man or specialist in any circumstances and, if so, whether he would cause the instant withdrawal of the circular.—Mr. WYNDHAM replied: The circular merely recited a rule which has been in operation for upwards of 30 years. The rule in no way prevents sick members of the force from employing medical men other than the police medical attendants. It merely points out that such medical assistance cannot be paid from public funds. It is not proposed to withdraw the circular.

WEDNESDAY, AUGUST 12TH.

Grievances of Irish Medical Officers.

Dr. THOMPSON asked the Chief Secretary to the Lord Lieutenant of Ireland whether the Irish Poor-law medical officers would be afforded any, and what, opportunity of having their alleged grievances inquired into by the Government and whether he would explain the reason why no notice had been taken hitherto of their remonstrances.—Mr. WYNDHAM replied: Any report which the Poor-law medical officers may make in writing in respect of their alleged grievances will be considered. No such representations have recently been addressed to the Local Government Board.

BOOKS, ETC., RECEIVED.

An Address

ON

SCIATICA:

AN INQUIRY AS TO ITS REAL NATURE AND RATIONAL TREATMENT FOUNDED ON THE OBSERVATION OF UPWARDS OF 400 CASES.

Delivered at the Medical Graduates' College and Polyclinic

By WILLIAM BRUCE, M.D., LL.D. ABERD.

GENTLEMEN,—I propose to deal in this paper with the complaint known as sciatica and to lay before you for your consideration the theory which I have formed as to the real nature and seat of that disease. I venture to think that the views as to the etiology and pathology of sciatica which are at present accepted must be modified in the future and the treatment of this disease placed on a surer and more rational basis. My opportunities of seeing cases of sciatica are considerable. During the last 13 years I have taken short notes of 418 cases of this complaint, not to speak of nearly as many more I had seen in 20 years' previous practice but not recorded. This collection is more than double the number recorded by Fuller as observed by Valleix and himself. I find that the disease is, on the whole, more prevalent amongst men than women. Table I. shows that in the

TABLE I.—*Showing the Age and Sex Distribution.*

Years.	Males.	Females.	Total.
20-29	9	9	18
30-39	22	19	41
40-49	36	35	71
50-59	62	66	128
60-69	60	45	105
70-79	23	20	43
—	212	194	406

gr
bi
was distinctly more prevalent amongst men than women.

cases with which I have had to deal the proportion of males to females is as 100 to 90, whereas in the general population the ratio of males to females is 100 to 104. The preponderance, however, of males is not nearly so much as I find stated by other observers. For instance, in 124 cases reported by Valleix the proportion of males is 72 to 52, while Fuller gives as many as 61 to 14. As regards age incidence I find that the greatest number of cases occur between 50 and 59 years of age, followed closely by those from 60 to 69 years, though, as Table I. shows, no age except the very earliest is exempt from the possibility of attack. With regard to position in life my own impression is that it is as frequent amongst the poor as amongst the rich. It would not give fair results to quote my own statistics on this point. This opinion would be decidedly confirmed if we include cases of rheumatoid arthritis of the hip-joint, sciatica being, I believe, merely a preliminary stage of this crippling disease, and one from which the poor, for plain reasons, are likely to be greater sufferers than the rich.

The symptoms of a typical example of sciatica are something like the following. To begin with there is some feeling of soreness in the hip and thigh, varying in degree from tingling or a feeling of "pins and needles" to sharp pain. This pain is aggravated by movements of the leg or it may attack the unfortunate sufferer in bed at night. Certain kinds of movement originate or increase the painful feelings, notably the exertion of getting into bed or the attempt to cross the affected limb over the sound one. Along with this latter symptom there may be a certain amount of powerlessness to execute this particular movement. The patient almost always walks with a limp on the affected leg. When the pain is severe at night there is, as might be expected, a feeling of restlessness and, without actual startings, there are often small local cramps. A marked peculiarity of the pain is that after some time it comes to be complained of on the outer side of the leg, extending in some cases as low down as the heel. There are also occasional patches of anæsthesia, generally on the outside of the thigh or leg. *Such is a description of the symptoms of the complaint*; the signs are described by Osler as tenderness on pressure over the sciatic notch or in the middle of the thigh. He mentions also that there is tenderness on pressure on the lower part of the sacrum, also over the head of the fibula and behind the external malleolus and over the heel and toe, but not on the inside of the foot. Taylor's description is practically *identical.*

The pathology of sciatica as c
which I have had access is meag
indeed, a genuine neuritis, such
in a few cases. Osler affirms
nerve has been examined in several cases and that in the operation of stretching it has been observed to be swollen and in a condition of interstitial neuritis. Sciatica is a comprehensive term and one familiar, perhaps too familiar, both to the patient and to his physician. So much is this the case that I fear many medical men are content with the subjective evidence and neglect the objective aspects of the disease. Indeed, I can only thus explain the present persistent ignorance, if I may be allowed to use such a term, as to its real nature which seems universally to prevail. It is one of many examples of the dangers of generalising too much and of the mistaken idea that if we are able to label a complaint we, as a matter of course, know how to cure it. No belief could be more fatal to sound practice, not only in this case, but we may say in that of almost every ailment which afflicts humanity. In my early days I was content to accept, as I have said was the general rule, the patient's or his medical adviser's diagnosis and without any special local examination of the affected limb to proceed to treat sciatica by the usual round of waters, baths, and massage. The first clear indication for treatment I came to see as being imperative was the necessity for *rest* and the bad effects resulting from insisting on or allowing exercise or very rough or excessive massage of the limb. I was struck with this peculiarity in a disease which was supposed to depend to a large extent on mental conditions and which distraction of any kind should usually alleviate. Having thus become convinced of the absolute need for rest I began to think whether sciatica might not be an affection of the hip-joint. About this time I came across some remarks of a great surgeon, fortunately still left to us and to science, Mr. Jonathan Hutchinson, who was of the opinion that a certain number of cases of sciatica were really due to trouble in the joint. The next step in the history of the evolution of my opinion was naturally the *careful examination of the limbs of patients affected with* sciatica. At first, with the exigencies of a busy practice confined to a short season of the year, I did not carry out this examination so thoroughly as it should have been conducted, and even yet there are difficulties, especially, as you can understand, in the case of women, that prevent such a minute examination of the physical condition of the hip and its surroundings as ought to be gone through.

In examining a patient the subject of sciatica there is a certain routine which I have found from a lengthened experience to be best, and I would venture to recommend my professional brethren to follow the same method. Ask the patient to lie down, as he stands in his clothes, on his back on an even firm couch; then, bending the affected limb at the knee, perform the passive movements of flexion, external rotation, internal rotation, and extension by Thomas's method at the hip-joint of the affected leg. If the case be at all recent one or more of these movements will cause pain, very often sharp pain, as the patient's countenance frequently reveals. Having carefully noted these signs, then ask him to undress and proceed to inspect the gluteal region. With the patient lying flat on his face and relaxing his muscles, you note whether there is wasting in this region or a diminution in the original number of the folds of the nates, and on comparing those of the opposite hip and the two thighs also together I venture to predict that in almost every case of sciatica you will discover softening or wasting and flattening of the hip muscles and more or less obliteration of the natal folds of the affected side. With the patient lying on his sound side you then proceed to inspect the capsule of the hip-joint. In some cases you will find it more prominent on the affected side and in a very few (but very seldom, for obvious reasons) you may be able to discover that there is increased heat over the joint. The position of the articulation is best made out by making sure of the exact relation of the anterior superior iliac spine and the highest point of the trochanter corresponding to the joint you suppose to be affected. The next thing to do is to examine carefully and without prejudice the presence or absence of tenderness on pressure over the capsule. This investigation has to be gone about keeping in view the fact that the patient is not an impartial witness, so to speak; he is very apt to confound symptoms with signs and his mind has been so intent on the suffering, say, in his foot that he refuses to help you in your attempts to discover the important sign you wish to make out—i.e., whether coxal tenderness be present or absent. When it is considerable you are independent of his preconceived ideas. In many cases moderate pressure with the point of the thumb over some part of the capsule causes so much pain that he winces unmistakeably. Of course, to make yourself certain you compare the two sides and by all means follow the line of the sciatic nerve and try to discover whether there is or is not tenderness on pressure along its course.

But in order to draw a proper picture of sciatica it is necessary to consider some general questions which bear very strongly on its essential features; and the first matter to which I ask your attention is the nature and origin of pain. In dealing with this branch of my subject I scarcely need to apologise for making reference to Hilton. His book is one which should be in the hands not only of every young practitioner but it deserves to be continually consulted by us older men. In summarising the lectures on Rest and Pain as delivered by him before the Royal College of Surgeons of England more than 40 years ago he says "that every pain has its distinct and pregnant signification if we will but carefully search for it." And again: "I have striven by the agency of a more complete anatomy to render plain the meaning of pains which are obscure." Further on he says: "From the pain which follows the intrusion of a particle of dust into the conjunctiva to the most formidable diseases we have to treat pain the *monitor*." From beginning to end of his discourse he dwells on the absolute necessity of following up the pain to its real source and by very numerous examples he enforces this lesson on his readers. The causes of pain he searches for by a study of the anatomy of the nerves and he does not rest with mere empty phrases, such as neuritis, neuralgia, &c. He goes on till he reaches the real origin of the causes of suffering. Thus, without exception, from one end of the book to the other he finds no instance in which nerve trunks are affected but rather the ultimate endings of their filaments. Has not nature arranged her lines of communication so as to carry messages correctly between those minute organs of sensation and the centres of motion and feeling? And is it likely that on the face of it she should have so constructed her telegraphic circuits that a mere passing influence, such as cold, heat, or even a certain amount of pressure, would seriously interfere with her perfect economy? Who in our day would refer toothache to anything else but to something which, like caries, has its source in some distinct *local* mischief either in the teeth or their sockets? It may be said, What, then, of trigeminal neuralgia? I am not prepared to deny that a continual series of shocks shall not injure the merely conductive parts of the nerve, just as the wire carrying an electric current may not be altered so as to affect its powers of conduction. Yet from some little study of that fell disease—tic doloureux—I boldly affirm that in every such case the pain originally starts from the sensory extremities of the nerve affected and that anything more essentially barbarous in the way of surgery than the excision of a portion of its substance or of the entire Gasserian ganglion I cannot conceive, unless it be forcible stretching of the sciatic nerve for sciatica. There is very little serious pathological evidence of inflammatory matter except the assertions of some surgeons of having found adhesions between the nerve and its sheath, or a swelling or redness of its substance in the course of an operation. Surely some careful morbid anatomist would oftener have found something more distinctly abnormal.

It is said in almost all the books that tenderness on pressure of the nerve trunk is to be found in most patients, but in the many cases which I have observed closely I have made this sign out in only a very few. Again, why should there not be neuritis of such nerves as the ulnar, which lies so near the surface, as of the sciatic nerve? Oh, it is said, the latter is so much more exposed to injury. Is it really more exposed than the ulnar? I consider it nothing less than an accusation against the Master Builder of us all to make such a statement. A very little consideration will show that it is incorrect. The nerve trunk from beginning to end is elaborately protected and so ingeniously isolated and packed away as to be as little liable to injury and violence, consistent with the movements of the leg, as it is possible to make it. Everything, therefore, *a priori* points to the extrinsic origin of the pain of sciatica. Where, then, is the starting-point of the pain? I answer, In the hip-joint. I do not deny that it may have its origin in tumours pressing on the pelvic portions of the nerve or in very rare cases from the presence of large accumulations in the lower bowel. But with a long experience of over 30 years, during which time my attention has been specially directed to sciatica, I have never seen such causes excite real sciatic pains, although I have seen them affect the anterior crural nerve and its branches. If we assume that the origin of the pain we are dealing with is in the hip-joint, what are the proofs? I have said that the pain is extrinsic in origin. Where and what are the connexions between the hip-joint and the extremities of the sensory nerves which supply the skin of the outside of the leg and the heel? The nervous supply, according to Cunningham, is the following: 1. Anterior crural nerve. The posterior division supplies the quadriceps extensor muscles and gives off irregular branches to the hip-joint as well as to the knee-joint. 2. Obturator nerve. The anterior division supplies the hip-joint. 3. Sacral plexus. The nerves to the quadratus femoris and the gemellus inferior supply a twig to the hip-joint. To trace the connexion between the nerve-supply of the joint and the areas of the skin in which the pain is felt we find that the cutaneous branches of the above nerves, according to the same authority, are as follows: 1. The anterior division of the anterior crural supplies the internal cutaneous and middle cutaneous, the inner side of the thigh, and the back of the knee. The posterior division by the long saphenous supplies the inside and back of the leg. 2. The anterior division of the obturator nerve supplies cutaneous branches to the inside and back of the thigh. The posterior division supplies the knee-joint. 3. The sacral plexus supplies cutaneous branches to the heel and the skin of the leg below the knee, except to the inner side which is supplied by the long saphenous.

It is plain from the foregoing account that there is ample communication between the hip-joint and the skin of the thigh and leg to account for the referred pains from the joint to the cutaneous surfaces. Hilton's account of the nerve distribution[1] is as follows:—

> I shall not dwell upon the anatomy of the hip-joint except to remind you that its muscles perform their functions in groups, that each group has a trunk nerve of its own, and that each nerve contributes a branch to the hip-joint itself. A branch of the anterior crural nerve passes to the hip-joint, a branch of the obturator going to the capsular ligament and to the ligamentum teres, and a branch proceeding to the posterior aspect of the hip-joint from the sacral plexus which supplies the gemelli, the quadratus femoris, and the obturator internus. This anatomy should be borne in mind because it explains how it happens that the remote and sympathetic pains associated with an inflammatory condition or chronic disease of the hip-joint are not always found at the same part of the limb. We all know very well that in some cases of hip-joint disease one of the earliest symptoms is remote from the actual seat of mischief—namely, pain within the knee or on the inner side of the knee-joint; and we are familiar with the explanation of it—namely, that the obturator nerve, which contributes a branch to the ligamentum teres, sends a branch to the interior of the knee-joint, to the inner side of it, and sometimes even lower down. The inflammation or a diseased condition of this ligament necessarily involves the little branch of the obturator nerve and a "sympathetic" pain is produced at the other end of the same nerve on the other side of the knee or within the knee-joint. As it is frequently with the obturator, so it ought to be sometimes with respect to the other nerves of the hip-joint; but the frequency of this knee pain, whether within the knee-joint or on its inner side, indicates that the ligamentum teres is the most common seat of early disease. We observe this same "sympathetic" pain in old persons who may or may not have had a slight injury to the hip but in whom the ligamentum teres softens down and disappears. Such persons often complain of severe pain within or on the inner side of the knee-joint. Some years ago I saw a case in which, after injury to the hip, this symptom of pain in the knee-joint was well and early marked. Afterwards the limb was slightly shortened and the foot everted, imitating the reputed symptoms of fractured neck of the thigh bone. I subsequently examined this patient's hip-joint and found that the injury was confined to the ligamentum teres.

Here, then, we see two sources of fallacy which have existed in the diagnosis of hip-disease—one as to the position of the sympathetic pains and the other as to the non-existence of heat. If we say that the "sympathetic" pain is always on the inner side of, or within, the knee and we are called to a case where it does not exist, of course it excludes from our consideration hip-joint disease; or if we say that every inflamed joint is marked by an increase of heat and we are called to a case where this does not exist (but I think it is very rarely absent), of course that again would exclude hip-joint disease from our consideration.

I have tabulated 418 cases of sciatica of which I have had personal knowledge. All the cases came directly under my cognisance, most of them under my own care and treatment. I am sorry to say that I have not been able, for different reasons, to give all the details I should have wished to be in a position to present to you. One point I must regret not having kept an exact record of is *lameness* of the affected leg. I think I may fairly enough assume that it was present in the great majority of the cases. In only one do I find it noted that walking did not cause pain and lameness. In 283 cases not specially observed I found 61 with tenderness on pressure over the capsule of the hip-joint, whereas in 125 cases specially examined (see Table II.) on this and the following points affecting the movements of the hip-joint there was evidence of tenderness on pressure over the capsule in 55 per cent. In 39 per cent. there was pain on flexion, in 41 per cent. pain on rotation inwards, and in 38 per cent. on rotation outwards. In only a very limited number was there found manifest distension of the capsule—say 1 per cent.—and in still less a number—0·25 per cent.—was there any evidence of heat over the joint discovered. In 52 per cent. of the cases there was evidence of gout or rheumatism in other joints and in 22 per cent. there was evidence of the occurrence of lumbago. In 80 per cent. of the cases taken altogether one or other of the above symptoms was present. A small number of cases which had begun as sciatica had gone on to ankylosis of the joint and would have been set down as examples of rheumatoid arthritis of the hip.

TABLE II.—*Diagnostic Results obtained from 125 Specially Observed Cases.*

Gout or rheumatism	observed in	65	cases or	52	per cent.
Lumbago	,,	28	,,	22	,,
Pain on flexion... ...	,,	49	,,	39	,,
Pain on internal rotation	,,	51	,,	41	,,
Pain on external ,,	,,	48	,,	38	,,
Wasting of glutei ...	,,	49	,,	39	,,
Incomplete natal folds	,,	37	,,	30	,,
Tenderness over capsule	,,	69	,,	55	,,

One or other of these signs was observed in 100 cases, or 80 per cent.

TABLE III.—*Showing the Average Intensity of the Symptoms (when Observed).*

Pain on flexion	70	per cent.
Pain on internal rotation	60	,,
Pain on external ,, ...	60	,,
Wasting of glutei...	55	,,
Absence of natal folds	55	,,
Tenderness of capsule	60	,,

In 283 cases not specially observed tenderness over the capsule was noticed in 61, or 21 per cent., and gout or rheumatism in 140, or 48 per cent.

The following are still to be noted: One better, taking exercise; one, heat over the joint; four, fulness over the joint; and one, tenderness over the sciatic nerve.

What may be assumed as fair inferences from these data? I think it may be fairly said that sciatica is some affection of the hip-joint and not neuritis of the sciatic nerve, that it is connected with the gouty or rheumatic diathesis, and also with so-called mono-articular rheumatic arthritis of the hip. The flattening of the glutei and obliteration of the folds of the nates which were present in 39 and 30 per cent. respectively of the cases strongly support this contention. It has also to be remembered that the nerve-supply to these muscles comes not from the sciatic nerve but from the sacral plexus. On the other hand, if sciatica really were an affection of the sciatic nerve, why should not the muscles of the whole leg be affected and why should the wasting and other nerve derangements be so localised and not extend to the whole limb? Again, even those who speak of sciatica as being a true neuritis are forced to allow that the electrical reaction of degeneration of muscles is never present. This is still further shown by the fact that sciatica rarely if ever leads to a permanent affection of the nerves and muscles. Indeed, it is characteristic of the disease that the vast majority of cases recover in time—it may be long or short—and in my opinion the length is mainly dependent on the fact of sufficient rest having been given to the joint—though they may be attacked again and again. If we have really to deal with an inflammatory condition of the hip in gouty and rheumatic subjects (and surely there is no good reason for these diseases not attacking this as well as the other joints, although it may be admitted that these diseases have a partiality for the extremities of the circulation) there is abundant reason for prescribing rest. It is not so easy to say why it should be of such importance in a mere neuritis, although I confess that this argument cannot be pushed very far. Again, many cases are aggravated by too early massage and forced movements, as Buzzard says, while careful massage and cautious passive movements at a later stage are of the utmost value. Do not these results tell strongly in favour of the affection being connected with the hip-joint, being precisely what we find in gouty and rheumatic affections of the knee and other joints? So accomplished a physician as Osler advocates very strongly the need for rest to the affected limb and even goes the length of insisting upon the application of the long splint to the leg. One wonders how he did not take one step more and come to see that such a support fixes the hip-joint and by so doing relieves the pain, giving the articulation (just as in so-called strumous disease) the best chance for recovery. We have seen that there is no proof of any real neuritis of the sciatic nerve, that there are ample means of communication between the extremities of the nerves in the joint and the surface of the skin of the leg, that movements of the joint are often either limited in extent or cause pain or both, that the muscles most closely connected with the hip articulation become atrophied, that there is very often tenderness on pressure over the capsule of the hip-joint and even some swelling, and occasionally, but rarely for a manifest reason, a feeling of heat imparted to the hand, that sciatica is universally admitted to be related to gout or rheumatism in most patients, and lastly, that gout and rheumatism are actually simultaneously present in other articulations.

Most important of all is the fact that in almost every case of sciatica there is present lameness of the limb affected. The patient constantly limps when walking. It is true that a very small percentage of those I have recorded (in 1 in 400) the sufferer has felt better when taking exercise. This can easily be explained on the same principle as properly applied massage giving relief. Does not the surgeon (for I hold sciatica to be a surgical disease) in every other case of lameness of the lower extremities, and, indeed, in every affection of the movements of the upper limb, proceed primarily to consider which of the joint surfaces are diseased? If on careful examination there is found no clear evidence of any trouble anywhere but in the hip-joint, while there is such to be found in that articulation, are we not justified in assuming the cause of the lameness to be connected with this joint and in considering that sciatica means trouble in the hip-joint and as a rule nowhere else?

It is difficult, if not impossible, to prove statistically a connexion between sciatica and rheumatoid arthritis of the hip-joint. Where a pelvic deposit is found and still more when ankylosis has been established the case is set down at once in the category of so-called rheumatoid arthritis and is removed from that of sciatica. I can only state my belief that the one complaint merges into the other and that it is impossible at certain stages to distinguish between them and that they are in fact one disease, sciatica when unrelieved eventually terminating in rheumatoid arthritis which in its turn leads to bony deposits on the femur and also on the ilium, these changes again proceeding to ankylosis between the femur and the pelvis.

Seeing then that trouble of a gouty or rheumatic kind does account for all the signs and symptoms of sciatica, is there any necessity to look for other explanations of the pains? We have seen that there is no pathological evidence of the presence of neuritis. Neuralgia is too vague a term to found a decision upon. In the course of my studies of the disease I have come across the cases given by Fuller 40 years ago (six in all) in his well-known treatise on rheumatism which I think unconsciously prove that the view of sciatica originating in the hip-joint is the correct one.

In the first case the patient was "easy when lying down, but the least attempt at motion invariably caused acute pain in the hip, thigh, and leg. The act of coughing, sneezing, or laughing were also productive of an attack." In the second case "the act of coughing, sneezing, and the least attempt at motion in bed brought on a paroxysm (and so also did pressure, however slight, in the course of the nerve)." In the third case (sciatica in both legs) "any attempt at motion gave rise to involuntary starting of the limb." In the fourth case "his easy position was lying on his back in bed with his knee slightly flexed. There was not any tenderness of the nerve on pressure." In the fifth case "the pain extended from the left hip down to the ankle, but no specially tender spot could be discovered in the course of the nerve. The pain was of a dull wearing character but was much increased by action and every act of straining, as in coughing, sneezing, and the like." In every case the origin of pain in the joint seems a complete explanation of the symptoms. In one of the cases tenderness on pressure over the nerve is described as being present, while in two it is said to have been absent. That the extremities of the nerves supplying the skin over the course of the main nerve should have been excited, so to speak, in this one instance is surely not to be wondered at, even if the starting-point was in the hip-joint.

When we come to the question of the proper treatment for sciatica there is very little room for difference of opinion. The main point—rest for the articulation—is insisted on equally by the advocates of the view that sciatica is of the nature of neuritis as it is a necessity if the hip-joint be affected. Given so much, there is very little more demanded by the advocates of the latter theory. Blisters, for example, may do some good; and, at any rate, their proper application demands rest for some time in bed. And the same may be said of applications in the form of sedative lotions and fomentations. Cure by acupuncture has almost entirely disappeared, a proceeding much in vogue 30 years ago. So much for the local treatment in the early stages. Massage and electricity, it is generally allowed, are contra-indicated at this period of the illness. The greatest advocates for the seat of the complaint being in the hip-joint must allow that when the inflammatory period is past these remedies are of the greatest service. In the way of constitutional treatment anti-gout and anti-rheumatic remedies are recommended equally from both points of view. The use of oil of turpentine has undoubtedly proved of benefit, some say from its purgative effects. But may not that be the result of its diuretic action? This would hold good whether effusion was present in the nerve sheath or within the capsule of the joint itself. Calm consideration of the results of treatment will, I think, go to show that the theory of a hip-joint affection squares more readily with the facts than with the view commonly accepted that the disease is an affection of the sciatic nerve. If so, then we shall be founding our practice on a clearer and more distinct comprehension of the disease we have to treat and shall not be led away by false and ill-digested assumptions of the effects of so-called cures supported it may be by rash and over hasty observations.

PS. (August 15th, 1903).—I have been much struck in cases I have come across lately with the fact that the pain seems to be almost always limited at the commencement of the attack to the region of the hip. Why so, if the sciatic nerve be *primarily* affected?

A Clinical Lecture

ON

THE SIGNIFICANCE OF PAIN AND TENDERNESS IN CASES OF INFLAMMATION OF THE APPENDIX.

Delivered at the London Hospital on July 3rd, 1903,

By C. W. MANSELL MOULLIN, M.D. Oxon., F.R.C.S. Eng.,

SENIOR SURGEON AND LECTURER ON SURGERY AT THE LONDON HOSPITAL; EXAMINER IN SURGERY AT THE UNIVERSITY OF CAMBRIDGE.

Gentlemen,—The abdominal viscera are for the most part entirely insensitive to pain. The nerves with which they are supplied are not connected directly with that part of the brain which is concerned with the development of sensation. This has long been known to be true of individual organs under special conditions. An ulcer of the stomach, for instance, may exist, unknown and unsuspected, for an indefinite length of time until suddenly it perforates and sets up acute peritonitis. The intestine may be torn across inside the abdomen without the patient being aware at the moment that he has sustained any serious hurt. Great lengths of intestine have before now been cut away accidentally.[1] After colotomy, when an unnecessary amount of bowel protrudes at the artificial anus, the intestine may be divided with scissors, or cauterised, or held with artery forceps without a sign of pain. An ulcer may develop in the appendix and remain unnoticed, so far as pain is concerned, until the floor gives way. A loop of gangrenous bowel may be resected and sutured under the patient's eyes. I have known a man walk into hospital 24 hours after an accident with a ruptured bladder, only concerned because he did not pass any urine. Incising the stomach in gastrotomy or the intestine in enterostomy is not felt. Isolated facts of this kind have long been known; arguing from them it has been found possible to perform extensive operations upon many of the abdominal viscera under local anæsthesia, the wall of the abdomen only being rendered insensitive. On the other hand, a very slight stimulus that affects the parietal portion of the peritoneum causes acute pain. Dragging upon the mesenteric attachment, for instance, is very painful. I have known even the slight pull caused by placing a ligature around a protruding portion of the colon after colotomy to bring on an attack of colic. Applying Dupuytren's enterotome to the cæcum does the same. Lennander[2] has described a series of abdominal operations under local anæsthesia in which he carefully and systematically investigated this point, always with the same result. The least tension upon the root of the mesentery (not upon other parts of it) causes pain which is nearly always referred to the umbilicus. The effect is the same whether there is a free mesentery or whether the peritoneum is reflected from off the sides of the viscera, leaving a portion of the circumference of the bowel attached to the parietes by cellular tissue. Pressure, whether external, due to some cause acting upon the abdominal wall, or internal, arising from the mutual relations of adjacent viscera, has exactly the same effect. Applied to the viscera it is not felt. The wall of the bowel or of the stomach can be clamped with pressure forceps and the arteries tied without exciting the *least sensation*, so long, that is to say, as there is no traction. Applied to the parietal peritoneum, on the *other* hand, either directly at the edge of an incision or indirectly through the abdominal wall, the least touch is felt at once and most acutely.

---

[1] Fowler: Annals of Surgery, 1894, vol. xix.

[2] Centralblatt fur Chirurgie, Feb. 23rd, 1901, No. 8.

Inflammation of the parietal peritoneum or of the post-peritoneal cellular tissue, whether due to an irritant acting directly upon the serous surface or to absorption from some comparatively distant source of infection, naturally makes the parts that are sensitive already tenfold more so. The slightest traction becomes almost intolerable. On the other hand, inflammation has no effect whatever upon the visceral layer. The wall of the bowel, whether inflamed or not, is quite insensitive. It has no sensory nerves. It has been suggested by Lennander[3] that one source of abdominal pain may be the chemical action upon the nerves of toxins absorbed from the intestine and carried into the neighbourhood of the nerve twigs by the lymphatics without necessarily causing inflammation. This must be regarded as doubtful, or at least as not proven, and it follows, therefore, as a natural corollary from the above facts that in the absence of other mechanical stimuli the cause of abdominal pain and colic is either pressure or traction upon the branches of the spinal nerves which are distributed mainly, if not entirely, to the abdominal walls, and that the intensity of the pain (so for as the individual is concerned) depends upon the degree of traction or pressure on the one hand and upon the condition of the surrounding tissues as regards inflammation upon the other.

It follows, moreover, that in acute inflammation of the appendix (1) absence of pain is no indication that the most serious mischief is not going on. On more than one occasion I have operated and found the appendix on the point of giving way in spite of the patient's protestations that he had never had more than a twinge of pain. 2. The initial pain of acute inflammation of the appendix which is so commonly referred to the umbilicus is due to the peristaltic action of the cæcum or of the appendix dragging upon the attachment of the peritoneum to the abdominal wall. This is especially likely to occur when the appendix is fixed by adhesions or the mesentery is short or twisted upon itself. In one case of inflammation of the appendix in which Lennander was operating under local anæsthesia the slightest traction upon the anterior layer of the parietal peritoneum caused pain which the patient spontaneously described as exactly like that which he suffered during an attack. 3. The cessation of this umbilical pain without improvement in the other symptoms is due to cessation of the peristalsis caused by the inflammation having spread to the muscular coat of the bowel. When this occurs the wall of the bowel is no longer able to contract and this source of pain disappears. That this is so is shown by the fact, which I have often pointed out, that the cessation of the umbilical pain is coincident with the formation of a local swelling which at this stage of the disease is due to distension of the bowel and thickening of its walls by inflammatory exudation. 4. The development of local pain, which as a rule precedes by some short time the cessation of the umbilical pain, means that the inflammation has spread from the appendix to the parietal peritoneum or to the post-peritoneal cellular tissue. These are the only structures concerned (at this period of the disease) which are supplied with nerves capable of transmitting the sensation of pain. Absence of local pain does not indicate anything. Severe pain is of serious import, as it implies either wide extent or great severity of inflammation.

Tenderness on pressure in cases of inflammation of the appendix may be deep or superficial, or both deep and superficial tenderness may be present at the same time and in the same place. Deep tenderness (which I shall deal with first) is naturally restricted to those parts of the abdominal walls and viscera which are supplied with sensory nerves. The bowel itself, whether inflamed or not, is not tender on pressure except where it is in contact with the post-peritoneal cellular tissue, so that the pressure can be transmitted to this. The presence of deep tenderness in inflammation of the appendix indicates that the inflammation has spread to the parietal peritoneum or to the cellular tissue beneath it. Deep tenderness may be general all over the lower part of the abdomen, or it may be confined to, or, what is especially frequent, most marked at, one spot which is known as McBurney's point. "This point is very accurately in the adult from one and a half to two inches inside of the right anterior superior spinous process of the ilium on a line drawn to the umbilicus. In children it is, in proportion to their size, so much less distant from the spinous process. Occasionally this most sensitive spot will be found half an inch or so nearer the pubes and sometimes this sensitive area will be larger than usual, but from the first hours of the disease, even up to the end of several days, this sign may be clearly made out in every case." "In late stages of the disease this sign does not usually exist."[4] According to McBurney this spot, which is only to be made out by deep pressure, corresponds to the base of the appendix. In a measure this is correct, but it is more accurately described as corresponding to that part of the parietal peritoneum which is in closest and most immediate connexion with the lymphatics that run from the inflamed organ. These, conveying the toxins, or in many instances, no doubt, the organisms themselves, from the appendix, become inflamed. The inflammation spreads from their walls to the surrounding cellular tissue and the serous membrane near, and as a result the sensitiveness becomes so great that pressure, even weeks after the acute attack has subsided, causes pain.

As an assistance in diagnosis there can be no doubt of the value of this point. It is an indication that the parietal peritoneum at that spot is unduly sensitive from some cause, and by far the most common cause is the extension of inflammation from the appendix. But of course this is not the only cause, and as the lymphatics from other viscera contained in the abdomen and pelvis may either communicate with those from the appendix or lie in their immediate neighbourhood it is evident that a similar tender spot may occur in other circumstances. Like all the other symptoms of inflammation of the appendix it must not be taken by itself but in conjunction with the others that are present at the same time. In exceptional instances the most tender spot lies at the back immediately over the crest of the ilium. This is strongly suggestive of an appendix lying behind the colon or at least of inflammation spreading directly upwards in the subserous cellular tissue in that situation, a variety of inflammation of the appendix in which I have often found the constitutional symptoms to be far more important and serious than the local ones. More frequently there is a very tender spot near the brim of the pelvis, most easily reached through the wall of the rectum. In one case under my care contraction of the bladder was exceedingly painful. The appendix was adherent to it and the bladder when it contracted naturally dragged upon it and through it upon the parietal peritoneum. Wherever it occurs this deep local tenderness at the beginning of an attack indicates the part of the parietal peritoneum which is first involved. Later, when the inflammation has spread more widely, the local becomes merged in the general tenderness which extends all over the lower part of the abdomen. But in cases in which no operation is performed it may, like McBurney's spot, become evident again later; the inflammation subsides last in the part which was first and most severely attacked. I have seen this well marked on several occasions and no patient can be considered safe from a relapse so long as this tender spot persists.

In one case of peritonitis following inflammation of the appendix under my care local tenderness was entirely absent. I have known the same thing to occur after perforation of a gastric ulcer and I believe the explanation to be the same in both instances. In both there were a great deal of effusion into the general peritoneal cavity and but little evidence of reaction or inflammation, and in both I believe the nervous system was overwhelmed so suddenly, partly by the shock, partly perhaps by the rapid absorption of unusually virulent toxins, that it was incapable of feeling pain. Absence of deep tenderness, therefore, when other well marked symptoms of inflammation of the appendix are present, may be regarded as of very grave import.

In addition to this deep tenderness there is in most cases of inflammation of the appendix a very marked degree of cutaneous hyperæsthesia Some patients describe the sensation caused by touching the skin with the finger as tickling; to others it causes positive pain and they shrink even from the contact of the bedclothes. In the majority of instances the distribution of this cutaneous hyperæsthesia corresponds to the segmental area described by Head[5] as the eleventh dorsal, but the areas corresponding hypertrophy of the heart and chronic myocarditis. Some of the attacks are very much like the syncope anginosa of the older writers. In Cases 3 and 4 the symptoms were those of myocardial disease associated with dilatation of the heart. Case 5, the most characteristic instance of the group, presented an extraordinary series of vascular and cerebral manifestations.

[4] McBurney: Discussion before the Medical Society of New York February, 1891.

[5] Brain, vol. xvi.

CASE 2. *Unusual sensations in the chest; constantly recurring vertigo with slow pulse; subsequent attacks with complete loss of consciousness; pulse-rate usually as low as 28, sometimes sinking to 20; arterio-sclerosis; duration of the symptoms for about six years; sudden death; calcification of the coronary arteries and the root of the aorta, with hypertrophy of the left ventricle.*—The case is given in full in my lectures on angina pectoris (1895). Of the subsequent history Dr. Houston of Troy, New York, writes (Jan. 5th, 1897): "Mr. V.'s pulse continues at about 30 to the minute with an occasional intermittence. He has now very marked vertigo, perhaps 25 attacks each day, each time nearly but not quite losing consciousness. He has no headache, sleeps well, and says he is very comfortable except for these sinking 'spells' and weakness." Jan. 25th, 1898: "Mr. V. has had some very bad attacks of late. In the present month he has twice fallen to the sidewalk while conversing with friends, loss of consciousness being absolute." March 13th, 1898: "The attacks of vertigo with unconsciousness have occurred at shorter intervals through January and February. After a period of complete rest he improved somewhat; pulse-rate 27 to the minute." On March 2nd, 1899, the patient died suddenly. On the 8th Dr. Houston wrote: "The day before Mr. V. died he had an attack of syncope on the street. In the evening he felt unusually well and played checkers with his son. He retired early and slept well. In the morning he got up and had his tub and went back to bed in order to have his breakfast. Just as the tray came he fell back suddenly and in a few moments died." The necropsy showed extensive calcification of the coronary arteries and the root of the aorta, with hypertrophy of the left ventricle. Dr. Houston states that at times his pulse fell to as low as 20 to the minute. The usual rate was 28.

This very remarkable case illustrates the long duration of the affection, fully six years, the syncopal type, without apoplectiform symptoms or convulsions, and the coronary artery changes.

CASE 3. *Attack of faintness, with a slow pulse; great cardiac weakness with pallor and syncopal attack; gradual recovery.*—The patient, a man, aged 57 years, was referred to me by Dr. J. Newton on April 4th, 1900 The patient had been a hard-working man who had lived carefully and indulged in no excesses. He had not used tobacco or alcohol. He had typhoid fever 20 years previously. His mother died from heart trouble at the age of 63 years. Two brothers had died from heart trouble at the ages of 30 and 40 years respectively. Two weeks before the onset of the present illness he had had a great deal of extra work and worry. On Nov. 14th, 1899, while walking to his place of business he felt faint, continued to walk, though slowly, and had no pain. He went to his office, walked upstairs, chatted with his foreman, then started home quietly. He felt very faint and excessively weak and was breathing very slowly. When he got home he was very pale, the left foot was particularly cold, and the left hand was very pale. He had no pain. His pulse became exceedingly slow—down to 38 and even lower. From this time on he was in bed for two months and had constantly recurring attacks of great pallor and coldness with cardiac weakness and slow pulse. During this time he had two fainting attacks in which he got very pale and cold. The heart's action gradually strengthened and he was able to get up and to move about the room. He had since then gradually improved but had had to be very careful and to go very slowly. When last seen he complained of a remarkable tickling and feeling of numbness in the left hand and the left foot, with a sensation of pulsation in the fingers. He was a very healthy-looking man, of good colour, with a good complexion. The eyes were clear; there was slight arcus in the left. The pulse was 72 and regular; the tension was plus; the artery was distinctly sclerotic. The apex beat was not visible; there was no increase in the area of transverse cardiac dulness. At the apex both sounds were clear, the first being loud and ringing. The aortic second sound was not accentuated. Altogether he seemed remarkably well and it was difficult to believe that he had had such a serious cardiac attack only a few months before.

CASE 4. *Attacks of transient vertigo with pulse; syncopal attacks; cardiac dilatation with œdema and enlargement of the liver; gradual persistence of the bradycardia; sudden death.*—was a robust, healthy-looking man, aged 61 years, of good habits and good family history. Except mental overwork and the stress and strain associated there were none of the factors leading to arterio-sclerosis. When about 35 years of age he had severe burns of both hands and the face which had been long in healing. Many members of his family had a pulse-rate of about 60. In the spring of 1899 I saw him during convalescence from an attack of bronchitis and was then impressed with the feebleness of the heart sounds; the pulse was firm and full, not specially slow. In the autumn of the same year he had an attack of syncope and it was then noticed that the pulse was slow. He also had transient attacks of vertigo. Early in the spring of 1900 he had another very severe attack of syncope in Philadelphia with prolonged collapse and great feebleness of the heart. He recovered rapidly, but the pulse remained at about 35. In the summer he became very neurasthenic and was unable to stand slight noises and had a distressing feeling of tension in the head. In July, August, and September there were much flatulency and gastro-intestinal disturbance and on exertion a tendency to fainting. There were râles at the bases of the lungs, slight cough, swelling of the liver, and signs of cardiac insufficiency. It was impossible to feel the apex beat, the area of transverse dulness was increased, the sounds were muffled, and there was a soft apex bruit. He was under the care of Dr. Holford Walker of Toronto who had the advantage of the counsel of Dr. McPhedran and of Dr. Musser of Philadelphia. I also saw the patient early in August. Gradually the heart grew stronger but without any change in the pulse-rate, which was constantly between 30 and 40. On no occasion did I find a "coupled rhythm." From October, 1900, to January, 1902, he improved steadily and was able to take long walks and to get back much of his accustomed vigour. On the morning of Feb. 5th, while getting out of bed, he complained of not feeling very well, was nauseated, and fell back in the bed and died in a few moments.

CASE 5. *Fainting "spells" with slow pulse; slight arterio-sclerosis; epileptiform attacks; remarkable discrepancy between the heart and pulse rate; death in an attack.*—A man, aged 56 years, a farmer, was admitted to hospital on May 15th, 1900. He complained of dyspepsia and a nervous affection. There was nothing of any moment in his family history. When eight years old he had typhoid fever; as a youth he had malaria and at the age of 21 years he had measles. Twenty-five years before he had an attack of gravel. He had never had any venereal disease. His habits had been good. He used neither alcohol nor tobacco. He had been a large eater. Until five years previously he was a shoemaker. In August, 1899, he had two fainting "spells" which lasted for about 10 or 15 minutes. In November he began to notice that after exertion there was a feeling of suffocation. He had had to be extremely careful in his diet; if he took too much food or very indigestible articles he would feel sick at the stomach or everything would grow dim and misty before his eyes. He had had in all four severe fainting attacks, in each of which he was unconscious for at least ten minutes. He had had many of the mild, slight attacks. The patient was a fairly well nourished, well-built man; the mucous membranes were a little anæmic. The tongue was coated. There were no tophi. Dorsal decubitus; there were no cyanosis and no arcus; the pupils were equal and normal. The pulse was of good volume, of about normal tension, regular, and 28 to the minute; the vessel wall was distinctly felt but was not greatly sclerosed. He had a moderate grade of funnel breast; the expansion of the chest was good; the lungs were clear throughout. The point of the maximum impulse of the heart was seen and felt in the fourth interspace, 10 centimetres from the middle line and one centimetre inside the nipple line; there was no thrill. Absolute dulness began on the fourth rib and extended from the right sternal border to the point of maximum impulse in the fourth interspace. There was a loud well-marked first sound, with which there was a soft systolic bruit, traceable as far out as the anterior axillary line. The second sound was well heard and clear. Between the clearly heard heart beats at times there was a faint systolic sound heard after the first and separated from the next by a long interval. This abortive character of the alternate heart beat, "coupled rhythm," was noted on the edge of an incision or indirectly through the abdominal wall, the least touch is felt at once and most acutely.

Inflammation of the parietal peritoneum or of the post-peritoneal cellular tissue, whether due to an irritant acting directly upon the serous surface or to absorption from some comparatively distant source of infection, naturally makes the parts that are sensitive already tenfold more so. The slightest traction becomes almost intolerable. On the other hand, inflammation has no effect whatever upon the visceral layer. The wall of the bowel, whether inflamed or not, is quite insensitive. It has no sensory nerves. It has been suggested by Lennander[3] that one source of abdominal pain may be the chemical action upon the nerves of toxins absorbed from the intestine and carried into the neighbourhood of the nerve twigs by the lymphatics without necessarily causing inflammation. This must be regarded as doubtful, or at least as not proven, and it follows, therefore, as a natural corollary from the above facts that in the absence of other mechanical stimuli the cause of abdominal pain and colic is either pressure or traction upon the branches of the spinal nerves which are distributed mainly, if not entirely, to the abdominal walls, and that the intensity of the pain (so far as the individual is concerned) depends upon the degree of traction or pressure on the one hand and upon the condition of the surrounding tissues as regards inflammation upon the other.

It follows, moreover, that in acute inflammation of the appendix (1) absence of pain is no indication that the most serious mischief is not going on. On more than one occasion I have operated and found the appendix on the point of giving way in spite of the patient's protestations that he had never had more than a twinge of pain. 2 The initial pain of acute inflammation of the appendix which is so commonly referred to the umbilicus is due to the peristaltic action of the cæcum or of the appendix dragging upon the attachment of the peritoneum to the abdominal wall. This is especially likely to occur when the appendix is fixed by adhesions or the mesentery is short or twisted upon itself. In one case of inflammation of the appendix in which Lennander was operating under local anæsthesia the slightest traction upon the anterior layer of the parietal peritoneum caused pain which the patient spontaneously described as exactly like that which he suffered during an attack. 3. The cessation of this umbilical pain without improvement in the other symptoms is due to cessation of the peristalsis caused by the inflammation having spread to the muscular coat of the bowel. When this occurs the wall of the bowel is no longer able to contract and this source of pain disappears. That this is so is shown by the fact, which I have often pointed out, that the cessation of the umbilical pain is coincident with the formation of a local swelling which at this stage of the disease is due to distension of the bowel and thickening of its walls by inflammatory exudation. 4. The development of local pain, which as a rule precedes by some short time the cessation of the umbilical pain, means that the inflammation has spread from the appendix to the parietal peritoneum or to the post-peritoneal cellular tissue. These are the only structures concerned (at this period of the disease) which are supplied with nerves capable of transmitting the sensation of pain. Absence of local pain does not indicate anything. Severe pain is of serious import, as it implies either wide extent or great severity of inflammation.

Tenderness on pressure in cases of inflammation of the appendix may be deep or superficial, or both deep and superficial tenderness may be present at the same time and in the same place. Deep tenderness (which I shall deal with first) is naturally restricted to those parts of the abdominal walls and viscera which are supplied with sensory nerves. The bowel itself, whether inflamed or not, is not tender on pressure except where it is in contact with the post-peritoneal cellular tissue, so that the pressure can be transmitted to this. The presence of deep tenderness in inflammation of the appendix indicates that the inflammation has spread to the parietal peritoneum or to the cellular tissue beneath it. Deep tenderness may be general all over the lower part of the abdomen, or it may be confined to, or, what is especially frequent, most marked at, one spot which is known as McBurney's point. "This point is very accurately in the adult from one and a half to two inches inside of the right anterior superior spinous process of the ilium on a line drawn to the umbilicus. In children it is, in proportion to their size, so much less distant from the spinous process. Occasionally this most sensitive spot will be found half an inch or so nearer the pubes and sometimes this sensitive area will be larger than usual, but from the first hours of the disease, even up to the end of several days, this sign may be clearly made out in every case." "In late stages of the disease this sign does not usually exist."[4] According to McBurney this spot, which is only to be made out by deep pressure, corresponds to the base of the appendix. In a measure this is correct, but it is more accurately described as corresponding to that part of the parietal peritoneum which is in closest and most immediate connexion with the lymphatics that run from the inflamed organ. These, conveying the toxins, or in many instances, no doubt, the organisms themselves, from the appendix, become inflamed. The inflammation spreads from their walls to the surrounding cellular tissue and the serous membrane near, and as a result the sensitiveness becomes so great that pressure, even weeks after the acute attack has subsided, causes pain.

As an assistance in diagnosis there can be no doubt of the value of this point. It is an indication that the parietal peritoneum at that spot is unduly sensitive from some cause, and by far the most common cause is the extension of inflammation from the appendix. But of course this is not the only cause, and as the lymphatics from other viscera contained in the abdomen and pelvis may either communicate with those from the appendix or lie in their immediate neighbourhood it is evident that a similar tender spot may occur in other circumstances. Like all the other symptoms of inflammation of the appendix it must not be taken by itself but in conjunction with the others that are present at the same time. In exceptional instances the most tender spot lies at the back immediately over the crest of the ilium. This is strongly suggestive of an appendix lying behind the colon or at least of inflammation spreading directly upwards in the subserous cellular tissue in that situation, a variety of inflammation of the appendix in which I have often found the constitutional symptoms to be far more important and serious than the local ones. More frequently there is a very tender spot near the brim of the pelvis, most easily reached through the wall of the rectum. In one case under my care contraction of the bladder was exceedingly painful. The appendix was adherent to it and the bladder when it contracted naturally dragged upon it and through it upon the parietal peritoneum. Wherever it occurs this deep local tenderness at the beginning of an attack indicates the part of the parietal peritoneum which is first involved. Later, when the inflammation has spread more widely, the local becomes merged in the general tenderness which extends all over the lower part of the abdomen. But in cases in which no operation is performed it may, like McBurney's spot, become evident again later; the inflammation subsides last in the part which was first and most severely attacked. I have seen this well marked on several occasions and no patient can be considered safe from a relapse so long as this tender spot persists.

In one case of peritonitis following inflammation of the appendix under my care local tenderness was entirely absent. I have known the same thing to occur after perforation of a gastric ulcer and I believe the explanation to be the same in both instances. In both there were a great deal of effusion into the general peritoneal cavity and but little evidence of reaction or inflammation, and in both I believe the nervous system was overwhelmed so suddenly, partly by the shock, partly perhaps by the rapid absorption of unusually virulent toxins, that it was incapable of feeling pain. Absence of deep tenderness, therefore, when other well-marked symptoms of inflammation of the appendix are present, may be regarded as of very grave import.

In addition to this deep tenderness there is in most cases of inflammation of the appendix a very marked degree of cutaneous hyperæsthesia Some patients describe the sensation caused by touching the skin with the finger as tickling; to others it causes positive pain and they shrink even from the contact of the bedclothes. In the majority of instances the distribution of this cutaneous hyperæsthesia corresponds to the segmental area described by Head[5] as the eleventh dorsal, but the areas correspondi to the tenth and twelfth are not uncommonly affected as well. The whole of these areas may be equally sensitive, or there may be one point in front or behind far more sensitive than the rest. Occasionally the hyperæsthesia is confined to one surface of the body, either anterior or posterior, and sometimes it is equally well marked on the left side as on the right. In one case under my care both the extent and the degree of hyperæsthesia were greater on the left side than on the right, without, so far as the appendix was concerned when it was exposed by operation, there being any apparent reason for it.

[3] Mittheilungen aus den Grenzgebieten der Medicin und Chirurgie, Band x., Heft 1 und 2.

[4] McBurney: Discussion before the Medical Society of New February, 1891.

[5] Brain, vol. xvi.

This local hyperæsthesia is evidence that the corresponding spinal centre is receiving from some part of the body to which its nerves are distributed stimuli of unwonted intensity and that it is in consequence unduly sensitive to ordinary impressions. These stimuli may come from the muscles. It is well known that the skin over the insertion of muscles that have been overworked is intensely hyperæsthetic. Or they may come from branches distributed to the abdominal wall. Quite recently I have had under my care a case of retroperitoneal abscess of very large size, not connected with any of the viscera, lying behind the liver and stomach, causing, as one of its most prominent symptoms, extreme sensitiveness of the skin on the right side of the body over the region of the sixth to the tenth dorsal segmental areas. Or they may come from the abdominal viscera, travelling to the centre along its visceral branches. But, as Head has pointed out,[6] they do not come from the peritoneum. So long as the inflammation is confined to the surface of the serous membrane there is no true cutaneous hyperæsthesia in peritonitis. Like McBurney's point, therefore, cutaneous hyperæsthesia over the region of the eleventh right dorsal segmental area may occur under a variety of conditions: the stimuli that cause the morbid activity of this centre may come along any of its branches, muscular, parietal, or visceral; but when the hyperæsthesia is definitely associated with other evidence pointing to inflammation of the appendix it may be taken as a clear indication that the wall of the appendix itself is involved and that, therefore, though the inflammation may subside, it will in all probability leave some permanent alteration in the appendix which will necessitate operation later.

There is one other point about the cutaneous hyperæsthesia in inflammation of the appendix which, if borne out by further observations, is of very great importance. Sudden cessation of the hyperæsthesia, without at the same time any corresponding improvement in the general symptoms, suggests very strongly that the appendix has become gangrenous and that immediate operation is absolutely necessary to prevent septic peritonitis. I have seen this in two well-marked cases of inflammation of the appendix and I have known a similar occurrence in a case of twisted ovarian pedicle in which also cutaneous hyperæsthesia was present at the first. The exact relation between these events is not obvious at first sight. It probably means that when the inflammation is so intense as to lead to gangrene either the nerves are no longer able to convey stimuli to the centre involved or that the centre itself is exhausted and can no longer respond. But whatever may be the explanation there can be no doubt of the fact that in these three cases the cessation of the hyperæsthesia coincided with the beginning of gangrene, and in such circumstances I regard nstant operation as imperatively required.

---

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—The following officers and members of the council for the session of 1903–4 were elected at the annual general meeting of this society on July 23rd. Council: Dr. J. Ford Anderson, Dr. C. W. Chapman, Mr. H. J. Curtis, Mr. H. L. Carre-Smith, Mr. Clinton T. Dent, Dr. C. N. Gwynne, Dr. E. Hobhouse, Dr. H. R. Hutton, Dr. R. Hutchison, Mr. F. Jaffrey, Dr. C. J. Macalister, Dr. A. Morison, Mr. R. H. Parry, Dr. J. P. Parkinson, Mr. George Pernet, Mr. H. Betham Robinson, Mr. Sydney Stephenson, Dr. S. B. Smyth, Mr. Harold J. Stiles, Dr. Frederick Taylor, Dr. James Taylor, Mr. J. W. Thomson Walker, Mr. R. H. A. Whitelocke, and Dr. A. W. Wills. Honorary treasurer: Mr. R. Clement Lucas. Honorary secretaries: Dr. George Carpenter, Dr. Theodore Fisher, and Dr. G. A. Sutherland.

ON THE SO-CALLED STOKES-ADAMS DISEASE (SLOW PULSE WITH SYNCOPAL ATTACKS, &c.).

BY WILLIAM OSLER, M.D. McGILL, F.R.C.P. LOND., F.R.S.,
PROFESSOR OF MEDICINE JOHNS HOPKINS UNIVERSITY, BALTIMORE.

DEFINITION.

Stokes-Adams disease is a clinical condition characterised by (1) a profound disturbance in the automatic mechanism of the heart—true bradycardia, hemisystole (false bradycardia), and allorythmia; (2) nervous symptoms—vertigo, syncope, pseudo-apoplexy, and epileptiform attacks; and (3) secondary symptoms—Cheyne-Stokes breathing, cardiac asthma, angina pectoris, and the vaso-motor accompaniment of profound heart-shock. The post-mortem changes are not constant. In a few cases coarse lesions of the nervous system have been found, in a small number no lesions whatever; in a large proportion of the cases arterio-sclerosis is present. The clinical picture is very variable—there are acute, rapidly fatal cases, chronic cases in which for years the patient has slow pulse with syncopal or pseudo-apoplectic attacks, and forms in which slight but well-characterised attacks occur at intervals in persons apparently well.

HISTORICAL NOTE.

Adams's description is of interest.[1] His patient, a man, aged 68 years, was of full habit and subject to oppression of breathing and cough. When seen he was just recovering from the effects of an apoplectic attack which had suddenly seized him three days before, but he was well enough to be about the house and even to go out. What attracted Adams's attention were the character of the breathing and the remarkable slowness of the pulse (30 to the minute). His regular attendant informed Adams that during seven years this patient had had not less than 20 apoplectic attacks. After a day or two of heaviness and lethargy he would fall down completely insensible and on several occasions he had hurt himself. The pulse would become slower than usual and the breathing loudly stertorous. He never had any paralysis after the attacks. Death followed an attack and the heart was found to be very fatty. The valves were sound. There was no statement about the coronary arteries. R. W. Smith[2] refers to this case, and states that he had also noted a condition of slow pulse with fatty heart.

Stokes's much more important contribution is entitled "Observations on some Cases of Permanently Slow Pulse." He describes the case of a man, aged 68 years, who had recurring fainting fits which left him without any unpleasant effects. During three years he had had at least 50 seizures. They were induced by any circumstance tending to impede or to oppress the heart's action, as sudden exertion or distended stomach. He was never convulsed. The duration of the attack was seldom more than four or five minutes and during this time he was perfectly insensible. He had never been paralysed. When admitted his general health seemed to be very good. There was an apex systolic bruit and the pulse was 28 to the minute. The arteries appeared to be in a state of permanent distension, "the temporal arteries ramifying under the scalp just as they are seen in a well-injected subject." An interesting feature in this case was that the patient could ward off attacks by a peculiar manœuvre. "As soon as he perceived symptoms of the approaching attack he directly turns on his hands and knees, keeping his head low, and by this means he says he often averts what otherwise would end in an attack." While his heart was beating only at 28 Stokes noticed that there were occasional semi-beats between the regular contractions, eight of them in the minute. On his readmission there was noted a new symptom, a remarkable pulsation in the right jugular vein, which was more than double the manifest ventricular contractions.

Beyond the occasional reports of cases not much of special importance has appeared in England on the subject. The condition is only mentioned incidentally in Allbutt's "System of Medicine." Gibson discusses it in a very good section in his "Diseases of the Heart." In France Charcot called attention to it in 1872, but to Huchard we owe a revival of interest, and in the various editions of his "Traité des Maladies du Cœur," under the name Stokes-Adams disease is found the best description in literature. In Germany the condition has not attracted attention, but within the past two years excellent papers have appeared by His, jun., Hoffmann, Jaquet, and Luce in the *Deutsches Archiv fur Klinische Medicin*. In the United States a most comprehensive study of the slow pulse was made by the late Dr. D. W. Prentiss[4] of Washington when he presented before the Association of American Physicians a remarkable case in which the condition had persisted for a period of nearly two years in association with very frequent fainting fits. Of the 94 cases which he abstracted from the literature there were 32 which belong to the condition under consideration. In the case reported by Dr. Prentiss there was a necropsy, and it is stated that neither the aorta nor the coronary artery was atheromatous, which is somewhat remarkable considering the extreme grade of sclerosis in the peripheral arteries. There were no lesions of the pneumogastric nuclei. In the discussion which followed the above case Dr. F. P. Kinnicutt and Dr. Jacobi narrated typical cases. In 1895 I described the condition briefly in my lectures on angina pectoris. Dr. R. T. Edes[5] has reported a series of cases and given an exhaustive analysis of the literature of the subject. Babcock has a good chapter in his recently issued work on "Diseases of the Heart."

CONDITIONS IN WHICH SLOW PULSE IS MET WITH.

1. *Physiological.*—The statement is made that dark persons and the dark races—e.g., Bretons—have a pulse rate below the average. It does not appear to be the case with the African race. I know a family most of the members of which have a pulse-rate of about 60; one son died from Stokes-Adams disease, another, perfectly healthy, has sometimes a pulse rate of only 48. Cases which can be called physiological are not very common. The slow pulse of Napoleon rests upon tradition;[6] it has been suggested that his epilepsy and attacks of apathy may have been associated features in a chronic form of Stokes-Adams disease. There are remarkable instances in the literature, many of them quoted by Dr. Edes, of persons in good health for years with a pulse-rate from 30 to 40. The slow pulse of old age may be considered normal, but the physiological limit is passed when with advancing arterio-sclerosis there are attacks of vertigo or syncope.

2. *Neurotic.*—1. Organic disease of the brain, the cord, or [illegible] fall below 60; in neurasthenia bradycardia may be a special feature. We must recognise, too, that severe and fatal attacks of Stokes-Adams disease may occur without any discoverable lesion in the nervous system, the heart, or the arteries.

3. *Toxic.*—(1) Inorganic poisons, such as lead; (2) bacterial poisons, as in diphtheria and typhoid fever; (3) vegetable poisons, as digitalis and tobacco; and (4) metabolic poisons, as in jaundice, uræmia, the puerperal state, and after prolonged exertion.

4. *Cardiac and cardio-vascular lesions.*—Valvular, myocardial, and arterial, alone or in combination; a large majority of the cases of bradycardia with nervous symptoms belong to this group.

VARIETIES OF STOKES-ADAMS DISEASE.

What is called Stokes-Adams disease is in reality a syndrome or symptom-complex, not a disease with constant anatomical lesions and a uniform etiology. The cases may be arranged in three categories.

1. *Post-febrile group.*—Following, more rarely in the course of, an acute infection—such as typhoid fever, diphtheria, pneumonia, scarlet fever, or rheumatism—bradycardia may occur with vertigo, syncope, or epileptiform seizures. A fair number of such cases are on record, and while Huchard is not inclined to regard them as instances of Stokes-Adams disease the main features are not to be distinguished. The attacks may recur for weeks, as in Schuster's case.[7] This form seems more hopeful, though the first attack may prove fatal. The following is a good illustration.

CASE 1.—A physician, aged 35 years, had on Feb. 8th, 1901, a streptococcus pharyngitis of moderate intensity, followed by acute nephritis. He convalesced satisfactorily and went to Florida on March 12th. He felt very well and had been taking a fair amount of exercise. At 4.55 A.M. on the 21st he was awakened out of sleep with a very peculiar sensation of numbness in the fingers and he felt faint and was covered with sweat. The pulse was only 16 to the minute but very forcible at the radial artery. He fainted and the physicians found him in a condition of extreme cyanosis and collapse, the sweat pouring from him, with a pulse-rate of about 20, quite regular, and the same at the heart and wrist. He was given hypodermic injections of ether and inhalations of oxygen. At 9 o'clock his pulse was 30. In the afternoon he regained consciousness and the pulse rose to 50. He was dazed and had no recollection of the attack. The cyanosis was extreme. On the next day his pulse was 60 but it was two or three days before he recovered completely. From the statements made by his physicians it was evident that his condition must have been critical. When I examined him on April 20th he was a robust, healthy-looking man, rather stout. The pulse was regular, with no intermission, and 76 to the minute. The apex beat was within the nipple line. The sounds were clear and of normal relative intensity; there was no change in the recumbent posture or bruit after exertion. The pupils were equal. The knee-jerks were present. There were no signs of any disturbance in the nervous system. In such a case it is reasonable to suppose that myocardial changes had followed the acute infection and were responsible for the profound disturbance in the automatic action of the heart with an associated acute dilatation. It is worth noting that in Case 11 the slow pulse was first noticed after an attack of pneumonia.

2. *Neurotic group.*—(1) With coarse lesions of the nervous system, as pressure on the medulla following injury (Holberton), narrowing of the vertebral canal (Lépine, Boffard), tumour pressing on the vagus, and degeneration of the trunks of the vagi. There has been no observation showing degeneration of the nuclei of the medulla. Charcot and Huchard have laid great stress on the bulbar features of the disease, but in the cases above referred to, particularly those of Holberton, Lépine, and Boffard, in which the symptoms were most characteristic, the lesions were extrinsic. A remarkable case is reported by Neuburger and Edinger in which a neurasthenic man, aged 46 years, with obstinate constipation, had vertigo and fainting attacks when at stool. For nine days before his death the attacks were associated with deviation of the head and eyes and a pulse-rate of 18 to the minute. The necropsy showed absence of the right lobe of the cerebellum and a varix close to the accessorius nuclei, with beginning hæmorrhagic infarction. (2) Without recognisable lesions. Typical attacks of Stokes-Adams disease of maximum severity are on record in which the most careful examination has failed to find any changes in the heart, the arteries, or the nervous system. Dr. Edes's first case, that of a woman, aged 50 years, with a very neurotic history, hadfor seven or eight months recurring seizures, with loss of consciousness, &c., in which the pulse fell to 20 to the minute. She died in an attack; the necropsy made by Dr. Councilman was negative.

3. *Arterio-sclerotic group.*—In this group there are obvious changes in the circulatory system. So large is the majority of the cases in this division that Huchard's dictum is justified, "L'étiologie est cette de la sénilité artérielle." My experience is confined almost entirely to this form. The histories, which I have condensed as much as possible, give a fair picture of the phases and forms of this remarkable condition.

CLINICAL HISTORIES.

All my cases, 12 in number, were in males; three of the patients were above 76 years of age and six were between 50 and 70 years of age. The youngest was 35 years old, the case following a streptococcus infection. Excluding this patient, my cases fall into three categories—a group of five cases with very severe and acute symptoms; a senile goup of four cases; and a milder form in younger men, two cases.

I.—SEVERE CASES.

The patients in the severe cases are men as a rule in the pre-senile stage and they present well-marked cardio-vascular lesions. In Case 2 there was extensive calcification of the coronary arteries and of the [illegible]

[illegible]

hypertrophy of the heart and chronic myocarditis. Some of the attacks are very much like the syncope anginosa of the older writers. In Cases 3 and 4 the symptoms were those of myocardial disease associated with dilatation of the heart. Case 5, the most characteristic instance of the group, presented an extraordinary series of vascular and cerebral manifestations.

CASE 2. *Unusual sensations in the chest; constantly recurring vertigo with slow pulse; subsequent attacks with complete loss of consciousness; pulse-rate usually as low as 28, sometimes sinking to 20; arterio-sclerosis; duration of the symptoms for about six years; sudden death; calcification of the coronary arteries and the root of the aorta, with hypertrophy of the left ventricle.*—The case is given in full in my lectures on angina pectoris (1895). Of the subsequent history Dr. Houston of Troy, New York, writes (Jan. 5th, 1897): "Mr. V.'s pulse continues at about 30 to the minute with an occasional intermittence. He has now very marked vertigo, perhaps 25 attacks each day, each time nearly but not quite losing consciousness. He has no headache, sleeps well, and says he is very comfortable except for these sinking 'spells' and weakness." Jan. 25th, 1898: "Mr. V. has had some very bad attacks of late. In the present month he has twice fallen to the sidewalk while conversing with friends, loss of consciousness being absolute." March 13th, 1898: "The attacks of vertigo with unconsciousness have occurred at shorter intervals through January and February. After a period of complete rest he improved somewhat; pulse-rate 27 to the minute." On March 2nd, 1899, the patient died suddenly. On the 8th Dr. Houston wrote: "The day before Mr. V. died he had an attack of syncope on the street. In the evening he felt unusually well and played checkers with his son. He retired early and slept well. In the morning he got up and had his tub and went back to bed in order to have his breakfast. Just as the tray came he fell back suddenly and in a few moments died." The necropsy showed extensive calcification of the coronary arteries and the root of the aorta, with hypertrophy of the left ventricle. Dr. Houston states that at times his pulse fell to as low as 20 to the minute. The usual rate was 28.

This very remarkable case illustrates the long duration of the affection, fully six years, the syncopal type, without apoplectiform symptoms or convulsions, and the coronary artery changes.

CASE 3. *Attack of faintness, with a slow pulse; great cardiac weakness with pallor and syncopal attack; gradual recovery.*—The patient, a man, aged 57 years, was referred to me by Dr. J. Newton on April 4th, 1900 The patient had been a hard-working man who had lived carefully and indulged in no excesses. He had not used tobacco or alcohol. He had typhoid fever 20 years previously. His mother died from heart trouble at the age of 63 years. Two brothers had died from heart trouble at the ages of 30 and 40 years respectively. Two weeks before the onset of the present illness he had had a great deal of extra work and worry. On Nov. 14th, 1899, while walking to his place of business he felt faint, continued to walk, though slowly, and had no pain. He went to his office, walked upstairs, chatted with his foreman, then started home quietly. He felt very faint and excessively weak and was breathing very slowly. When he got home he was very pale, the left foot was particularly cold, and the left hand was very pale. He had no pain. His pulse became exceedingly slow—down to 38 and even lower. From this time on he was in bed for two months and had constantly recurring attacks of great pallor and coldness with cardiac weakness and slow pulse. During this time he had two fainting attacks in which he got very pale and cold. The heart's action gradually strengthened and he was able to get up and to move about the room. He had since then gradually improved but had had to be very careful and to go very slowly. When last seen he complained of a remarkable tickling and feeling of numbness in the left hand and the left foot, with a sensation of pulsation in the fingers. He was a very healthy-looking man, of good colour, with a good complexion. The eyes were clear; there was slight arcus in the left. The pulse was 72 and regular; the tension was plus; the artery was distinctly sclerotic. The apex beat was not visible; there was no increase in the area of transverse cardiac dulness. At the apex both sounds were clear, the first being loud and ringing. The aortic second sound was not accentuated. Altogether he seemed remarkably well and it was difficult to believe that he had had such a serious cardiac attack only a few months before.

CASE 4. *Attacks of transient vertigo with permanent slow pulse; syncopal attacks; cardiac* [illegible] *œdema and enlargement of the li*[illegible] *persistence of the bradycardia; sudden death.*—The patient was a robust, healthy-looking man, aged 61 years, of good habits and good family history. Except mental overwork and the stress and strain associated there were none of the factors leading to arterio-sclerosis. When about 35 years of age he had severe burns of both hands and the face which had been long in healing. Many members of his family had a pulse-rate of about 60. In the spring of 1899 I saw him during convalescence from an attack of bronchitis and was then impressed with the feebleness of the heart sounds; the pulse was firm and full, not specially slow. In the autumn of the same year he had an attack of syncope and it was then noticed that the pulse was slow. He had had transient attacks of vertigo. Early in the spring of 1900 he had another very severe attack of syncope in Philadelphia with prolonged collapse and great feebleness of the heart. He recovered rapidly, but the pulse remained at about 45 In the summer he became very neurasthenic and was unable to stand slight noises and had a distressing feeling of tension in the head. In July, August, and September there were much flatulency and gastro-intestinal disturbance and on exertion a tendency to fainting. There were râles at the bases of the lungs, slight cough, swelling of the liver, and signs of cardiac insufficiency. It was impossible to feel the apex beat, the area of transverse dulness was increased, the sounds were muffled, and there was a soft apex bruit. He was under the care of Dr. Holford Walker of Toronto who had the advantage of the counsel of Dr. McPheadan and of Dr. Musser of Philadelphia. I also saw the patient early in August. Gradually the heart grew stronger but without any change in the pulse-rate, which was constantly between 30 and 40. On no occasion did I find a "coupled rhythm." From October, 1900, to January, 1902, he improved steadily and was able to take long walks and to get back much of his accustomed vigour. On the morning of Feb. 5th, while getting out of bed, he complained of not feeling very well, was nauseated, and fell back in the bed and died in a few moments.

CASE 5. *Fainting "spells" with slow pulse; slight arterio-sclerosis; epileptiform attacks; remarkable discrepancy between the heart and pulse rate; death in an attack.*—A man, aged 56 years, a farmer, was admitted to hospital on May 15th, 1900. He complained of dyspepsia and a nervous affection. There was nothing of any moment in his family history. When eight years old he had typhoid fever; as a youth he had malaria and at the age of 21 years he had measles. Twenty-five years before he had an attack of gravel. He had never had any venereal disease. His habits had been good. He used neither alcohol nor tobacco. He had been a large eater. Until five years previously he was a shoemaker. In August, 1899, he had two fainting "spells" which lasted for about 10 or 15 minutes. In November he began to notice that after exertion there was a feeling of suffocation. He had had to be extremely careful in his diet; if he took too much food or very indigestible articles he would feel sick at the stomach or everything would grow dim and misty before his eyes. He had had in all four severe fainting attacks, in each of which he was unconscious for at least ten minutes. He had had many of the mild, slight attacks. The patient was a fairly well-nourished, well-built man; the mucous membranes were a little anæmic. The tongue was coated. There were no tophi. Dorsal decubitus; there were no cyanosis and no arcus; the pupils were equal and normal. The pulse was of good volume, of about normal tension, regular, and 28 to the minute; the vessel wall was distinctly felt but was not greatly sclerosed He had a moderate grade of funnel breast; the expansion of the chest was good; the lungs were clear throughout. The point of the maximum impulse of the heart was seen and felt in the fourth interspace, 10 centimetres from the middle line and one centimetre inside the nipple line; there was no thrill. Absolute dulness began on the fourth rib and extended from the right sternal border to the point of maximum impulse in the fourth interspace. There was a loud well-marked first sound, with which there was a soft systolic bruit, traceable as far out as the anterior axillary line. The second sound was well heard and clear. Between the clearly heard heart beats at times there was a faint systolic sound heard after the first and separated from the next by a long interval. This abortive character of the alternate heart beat, "coupled rhythm," was noted on admission At the aortic area the heart sounds were enfeebled and there was a soft systolic murmur The second sound was not accentuated The abdomen looked natural and there was no tenderness on palpation The border of the liver was not palpable, the spleen was not enlarged. There was no œdema of the legs or feet

The case is of sufficient interest to give in some detail On May 16th the patient felt dizzy and at 4 P M he suddenly became very pale and fainted, remaining unconscious for ten minutes The pulse fell to 15 beats per minute Between 4 and 8 P M he had four such attacks, the pulse varying from 15 to 20 beats per minute There was sweating with each attack After the last attack of syncope he vomited The night nurse reported that on several occasions the pulse was as low as 15 beats He slept comfortably and in the morning seemed all right On the 17th, at the visit at 9 A M, I found the patient with a pulse rate of 18 Both sounds had a very normal character at the apex The systolic bruit had the greatest intensity over the body of the heart The percussion note was clear over the manubrium There was no tracheal tugging On the 19th, while making the morning visit, I saw the patient in two attacks, each of which lasted about half a minute The eyes were turned to the left and became fixed, the muscles of the face twitched and the hands twitched slightly It resembled a slight epileptic attack The pulse at the wrist was 12, and the cardiac impulses corresponding to them were strong and easily seen In the jugular veins there were fluttering systolic impulses, quite well defined, but difficult to count, about 120 to the minute On careful inspection of the cardiac area there were seen in the fourth and fifth interspaces small, regular, systolic impulses, exactly 100 to the minute Corresponding to these there could be heard faint systolic sounds at the same rate During the night the patient had a severe attack of vomiting and had frequent syncopal attacks Dr Futcher noted that while the pulse was beating at 12 to the minute auscultation over the heart gave 143 feeble beats to the minute, each eleventh or twelfth beat being forcible, with a loud first sound, and corresponding to the one recorded in the radials On the 20th the patient had some hiccough and at midnight there was typical Cheyne Stokes breathing The heart could be seen beating at 95 to the minute but the pulse was only 19 at the wrist On the 23rd the patient had been better for the past two or three days The pulse had been at about 20 at the wrist and 84 at the heart On the 26th the patient had a persistent pallor, the pupils were small and equal, the pulse was full, 19 to the minute at the wrist and 74 at the heart On the 29th at the time of the visit the pulse was 28 at the wrist The small beats were not visible at the point of maximum cardiac impulse, where the impulses corresponded with the pulse at the wrist, but on auscultation between each of the forcible impulses, which shook the whole front of the chest, there was heard a little, soft, faint, systolic sound, which was not expressed at the apex as a visible or palpable impulse and was not felt at the wrist The pulsations in the jugular vein were very evident but it could not be determined if they corresponded with the total number of ventricular beats At 9.30 P M the patient had an attack of unconsciousness lasting for several minutes, followed by dyspnœa and afterwards Cheyne Stokes breathing On the 30th, at 10 A M, while the nurse was giving him his bed bath he suddenly vomited and immediately afterwards became perfectly rigid and unconscious and cyanosed Before chloroform could be administered the muscles relaxed, the patient gave a few gasps at rather long intervals, and died without regaining consciousness During the attack the pulse was not perceptible at the wrist Artificial respiration was performed without any result There was a slight trace of albumin in the urine and there were a few hyaline and granular casts There was no necropsy

Another case of the same intensity may be referred to On May 13th, 1902, I saw in the afternoon at the Union Protestant Infirmary, with Dr Hamburger, a man, aged 45 years, who illustrated all the symptoms of this severe type of the Stokes Adams disease He was a stout, healthy looking man. He shook hands with me as I went in and then gradually closed his eyes in an apathetic way The face and general surface of the skin were a little suffused The pulse was 20 to the minute, there was slight sclerosis of the artery, no special increase in tension was present. There were no intermediate beats of the radial pulse He was rather stout and the apex beat was not easily visible, but the slow heart beats were palpable Intermediate small beats could neither be seen nor felt There was considerable increase in the transverse area of cardiac flatness In the neck the visible pulsation of the carotids was very plain, 20 to the minute, and there were in the suprasternal notch and just along the sterno cleido muscles on either side two or three tremulous venous impulses not so localised as in Cases 5 and 8 On auscultation at the apex both the first and second sounds were well heard With the first there was a rather rough grating murmur There were no intermediate sounds audible. Above the fourth costal cartilage, particularly at the midsternum, Dr Hamburger had noted between the sounds one or two distant soft sounds These I, too, could catch with distinctness Just after we had finished the examination the patient had in succession two epileptiform paroxysms The onset could be told at once as the beat of the heart stopped and could not be felt at the wrist or heard at the heart for from 15 to 20 and even as long as 35 seconds The convulsion was a general tremulousness, the face became slightly cyanotic, the breath was held, the eyes twitched and rolled up, and the muscles of the face twitched The paroxysms lasted for a few seconds only He came out of them very quickly and the face flushed with great rapidity and he seemed a little dazed He had as many as 150 of such attacks in the 24 hours The patient recovered from the serious condition and returned to his home in Washington A few months later he died during an attack

CASE 6 *Typical pseudo apoplectic attacks as described by Stokes, slow pulse, in some attacks convulsions, duration more than ten years* —While attending the meeting of the British Medical Association at Montreal in 1897 I saw at a club an old friend, a man aged about 60 years, who consulted me casually about distressing attacks of transient vertigo and others of a more severe nature in which he lost consciousness completely During the attacks he said that his pulse sank to 20 or even lower He said to me, "It is not at all improbable that I may have an attack at some time while you are in the club and I will tell the head waiter to notify you" On the following day, while I was at dinner, I was called hurriedly to the secretary's office and there I found my friend in an attack He had fallen unconscious, was breathing very heavily, almost stertorously, and had a very flushed face I thought at once that it was really an apoplectic stroke The pulse was very slow and very full, about 20 to the minute The arteries were very sclerotic The heart's action was very forcible and I could not hear with the unaided ear any intermediate beats or a murmur So alarming did I think his condition that I said to his servant that I thought it might be well to send for his physician and to have him bled, to which he replied that this was an ordinary attack, that he had seen him in many quite as severe, and that he rallied in the course of from 15 or 30 minutes I returned in the course of half an hour and found him up, feeling a little dazed and heavy in the head but quite himself In some of the attacks he stated that he had convulsions On March 3rd of the following year he wrote to me that he had been very much better He stated that he had had the fainting attacks and the slow pulse for many years Dr James Stewart, under whose care he was, told me that his attacks were often of the character of *petit mal* and were sometimes followed by motor aphasia, mainly of nouns The lowest pulse rate he had ever found was 21, but it had been as low as 18 He died during an attack The trouble had lasted for fully ten years He had painful neuromata along the extensor surface of the left arm and two in the left shoulder There was a curious relationship between the pain in these and the pulse rate, the slower the pulse the greater was the pain

II —SENILE CASES.

Not infrequently old men have bradycardia with attacks of vertigo, or of fainting or even of prolonged unconsciousness There may be in addition cardiac dyspnœa and Cheyne Stokes breathing The cases are more common, I think, than any description in the literature would lead one to suppose, particularly the incomplete forms, *forme fruste*, with vertigo

CASE 7 *Slow pulse, syncopal attacks, arthritis, possibly gout, pericarditis, death* —On Jan 16th, 1899, I saw, with Dr Hemmeter, a man, aged 72 years The patient, a very healthy man, had lived an active life, had been a hearty eater, and had been "fond of a glass of beer" He had had several attacks of arthritis, once or twice in his big toe During the past three years it had been noticed that his pulse was very slow, down to between 50 and 60, and he had had three syncopal attacks with pronounced bradycardia. In one of these he had fallen when at stool and was unconscious for some time, with a pulse-rate of 40. When I saw him he had slight arthritis, a temperature of 102°F., and a pulse of 56, full in volume. The vessel wall was moderately sclerosed. The heart sounds were clear. On the 18th I saw him again. There was then a very loud to-and-fro pericardial friction murmur. His temperature had kept up, the joint symptoms were better, but he evidently was not so well. The amount of urine was reduced and there were much albumin and numerous tube casts. He became very much worse during the next three days, became unconscious, Cheyne-Stokes breathing developed, and he died on the morning of the 23rd. There was no post-mortem examination.

CASE 8. *Attacks of vertigo and sudden weakness; slow pulse; arterio-sclerosis; sudden death.*—The patient, a medical man, aged 70 years, was seen in March, 1900. He had always been a strong, robust man; he had never been ill in his life and was unusually well and strong. He had been a devoted cigarette smoker for 40 years. He was not a heavy eater; he had drunk during and after the War of Secession, but had been a temperate man for 26 years. He had been gouty at times. He was a fairly hard worker. On Feb. 10th he had a "giddy spell" and felt a sudden weakness as though he wanted to lie down but did not faint. The attack lasted for an hour or two. He then noticed that his pulse was slow, only 40 to the minute. It did not reach the normal for a couple of days. His usual pulse had been from 72 to 76. He did not feel well for two days. Ten days later he had a second attack, felt giddy, and noticed that his pulse was again low and that it had remained low, once being as low as 38, occasionally rising to 42 and 44. When quiet he was comfortable. He staggered a little when he first got up. He had no pain about the heart. The pulse in the sitting posture after rest and quiet was just 40. There was moderate sclerosis of the arteries. The apex beat was diffusely visible just below the nipple. The beats at the apex were 40; there were no abortive heart systoles. There was an apex systolic bruit, not obliterating the first sound, and very faint at the aortic cartilage. No flatness was manifest over the manubrium. In the right side of the neck there was a pulse in the jugular vein which occurred in groups of three and which was twice as rapid as the pulse in the temporals. It looked just like a wavy venous impulse and was 80 to the minute. I saw this patient again twice. He improved for a time after the use of tobacco and the pulse-rate rose to 55. He had a return of the "sinking" attacks with bradycardia and I heard of his death during an attack in April, 1903.

It is remarkable for how long bradycardia and occasional fainting attacks may persist. In the following case the patient claimed that he had had a slow pulse for 30 years and that he had occasional fainting attacks.

CASE 9. *Stokes-Adams disease; slow pulse; syncope with anginal attack; cardiac dyspnœa; sudden death.*—The patient, a man, aged 74 years, was seen with Dr. McDowell, complaining of debility, with attacks of shortness of breath and palpitation. He was a thin, spare man and had a good colour. He had had a very healthy life without serious illnesses. Thirty years previously his son, at the time aged 12 years, had a fall and after feeling his pulse he felt his own and found that it was only 50 per minute. He consulted a physician who told him that his condition was serious and that he would not live long. He thought that he had had a slow pulse ever since until lately. For many years he had been subject to fainting attacks on extra exertion or on great mental emotion, but they had never been serious. Five years before, on the occasion of the fiftieth anniversary of his ordination, he preached and at the conclusion of his sermon he was seized with a pain of terrible severity in the region of the heart and down both arms. In the arms the pain was as intense and severe as the sharpest toothache. He was very faint and lost consciousness. He broke out into a profuse perspiration and the attack ended with severe diarrhœa. His pulse was very slow and three days after the attack the medical attendant said that his pulse was 38. Since that date he had not had any fainting attacks. He had felt on many occasions palpitation of the heart and irregularity and he had known that his pulse had been below 50. At night he would sometimes be aroused if he lay on the left side by a sudden sharp pain, as if something had grasped the heart. Within the past year he had had certain additional features. His pulse had become more rapid, having risen to above 70. He had had attacks of cardiac dyspnœa at night and was short of breath on exertion. That summer at the seaside he preached, took a great deal of interest in church matters, and seemed to have overtaxed his strength. He had become much more feeble. The patient's colour was good; there was no swelling of the feet; no arcus was present. The radials were stiff, with no calcification. The apex beat was in and just outside the nipple line. There was a soft systolic murmur and along the left sternal border a soft aortic diastolic which was heard only when the breath was held. Both sounds were rather feeble at the base. There was no tenderness over the course of the aorta. I saw this patient again with Dr. McDowell on Oct. 13th. He had been steadily failing, had much less ability to get about, and much shortness of breath, particularly at night. For the past two or three days he had been worse. On the previous evening he had an unusually severe attack of cardiac asthma and one attack was associated with a good deal of pain. I saw him at 5.30 in the afternoon. He was resting quietly, breathing easily. His pulse was 90 and of very good volume; there was no special tension. There was a soft apex systolic murmur, as at the previous examination. There was no gallop rhythm. His cardio-vascular condition seeemed to be extremely good. He was rather dull, did not care to be disturbed, and complained of feelings of great prostration and weakness. At 12.30 that night he died suddenly without awaking.

CASE 10. *Attacks of dyspnœa; slow pulse; two attacks of loss of consciousness; arterio-sclerosis; hypertrophy of the left ventricle.*—The patient, a man, aged 65 years, was seen on Dec. 14th, 1896, complaining of dyspnœa. On entering the room the patient was so short of breath that he had to wait several minutes before he could say what was the matter. With the exception of dyspepsia, which he had had at intervals for 30 years, he had been a very healthy man. He had not used alcohol or tobacco and had not had syphilis. He had diphtheria 10 or 12 years ago; he had not had rheumatic fever or gout. He had worked hard and recently had had business troubles and cares. For the past two or three months he had been getting short of breath, particularly on exertion. After proceeding thus far in the history I felt his pulse and was surprised to find it very slow, 40 to the minute. I then asked him about attacks of unconsciousness, of which he had made no mention, and got a history of two very remarkable seizures. In June, 1895, in Washington, after a couple of days of anxious business, he returned home one Thursday and just after dinner had a fainting attack. He did not know how long it lasted, but his family was very much alarmed and sent for a medical man; he was "off his head" for some time after the attack and talked foolishly. He was not able to leave the house for ten days. He had a second attack in June of this year. He was in the Custom House attending to some business and fell in a faint. He was unconscious for more than 20 minutes and was a good deal dazed after coming to. These were the only two attacks he had had. The patient was a tall man, with iron-grey hair and beard; he talked very deliberately and the expression was rather heavy and dull. The pulse when first counted was 40 per minute, full, slow, incompressible, anastomotic; the vessel wall was considerably thickened. The apex beat was in the fifth interspace, just below and a little outside the nipple line, forcible and punctuate. There was no thrill. On palpation in the second right interspace and second right costal cartilage there was to be felt an unusually loud diastolic snap. The limit of cardiac flatness was on the fourth rib at the right sternal margin and just at the apex beat. At the apex both sounds were heard, with the first a soft systolic murmur. At the second right interspace there were a soft systolic murmur and a second sound of most unusual and remarkable intensity, without any amphoric quality, sometimes single, sometimes distinctly reduplicated. I saw the patient again on June 27th, 1897. He had been much better; the slow pulse was not permanent but at times it was as low as 40.

III.—CASES OF SLOW PULSE WITH OCCASIONAL SYNCOPAL ATTACKS IN YOUNGER, HEALTHY MEN.

CASE 11. *Attacks of fainting for five years; slow pulse; arterio-sclerosis; good general health; appendicitis; operation; recovery.*—The patient, a man, aged 40 years, was seen on May 20th, 1901, complaining of attacks in which he fell and lost consciousness. The patient had been a healthy man, very active and vigorous. For many years he had had at times rheumatic pains. After an attack of pneumonia, nearly

20 years previously, it was noticed that he had a slow pulse but he did not remember the rate. Five years previously he had his first attack of fainting. He felt nauseated and faint but recovered very rapidly. A few days later he had a second attack. During that summer he had a good many and he had had them at intervals ever since. He felt in them as though everything stopped and then he would fall. There were no movements in the attacks. He was more apt to have them when he was tired or after any special excitement. In the attacks he either fainted away completely or could with difficulty keep himself from fainting by [illegible] tion. The heart was not enlarged. The sounds were clear; the aortic second sound was a little accentuated. The radials were distinctly sclerotic. The patient was admitted to the hospital, where he had an attack of appendicitis, of which he had had several previously, and he was transferred to the surgical side for operation. Very many observations were made upon his pulse and heart. The rate was usually about 50. The day before operation it was 40; just after the operation it rose to 90. There was no "coupled rhythm." He remained in hospital until June 3rd, during which time the range of the pulse was from 40 to 65. There was no hemi-systole. On the occasion of his visit to me I made him go out and walk briskly and when he came in his pulse rose to 110. He was a very healthy, active man and said that he had got accustomed to the fainting attacks

CASE 12. *Syphilis at 23 years of age; for six months recurring attacks of vertigo; two attacks of great severity; permanent slow pulse of 28.*—A robust, healthy-looking man, [illegible] a moment or two as though he was about to fall, but quickly gained control without struggling or swaying; while he was undressing he flushed a moment and said, "There, that was a slight one." He had many of these, often three or four in the day, and any excitement was apt to induce them. Twice he had had more serious attacks in which he had become faint and had had to hold on to something to keep from falling. He did not lose consciousness but felt a sensation of "utter goneness," as he expressed it, and then broke out into a profuse sweat. There were a sensation, too, of stuffiness in the throat and a wheezing in the tubes. Shortly after his attack of faintness the medical attendant noticed that his pulse was very slow and it had ranged ever since from 28 to 36. He had no abnormal sensations about the heart itself. He felt well and was vigorous but he had become much alarmed since the onset of the severer attacks. He had been a vigorous, muscular man; he had used much tobacco and alcohol in moderation. He had had syphilis but was thoroughly treated for two years. I dictated the following note:—"Healthy-looking man of good colour. Pulse 28, full; radials easily felt. Visible pulsation in cardials and a fluttering venous impulse difficult to count but about double the rate in the carotid. Apex beat not visible, not palpable; no increase in the area of transverse cardiac flatness Both sounds audible at apex; no intervening beat to be heard at apex or base. Aortic second sound accentuated. After exertion the pulse-rate rose to 40. Examination of the other organs was negative."

I have permission to quote the following remarkable description of his own case by an army officer who has consulted me by letter on several occasions and who has been under the care of Dr. R. H. Babcock and Dr. E. F. Wells of Chicago:—

January 5th, 1903

DEAR SIR,—While in Germany in the summer and fall of 1900, taking a course of the Schott bath treatment for an affection of the heart, I took [illegible] sult several German [illegible] n was Professor Dr [illegible] ses of the Circulatory [illegible] n my return to this [illegible] This I was unable to [illegible] me to Europe upon [illegible] e West I have been [illegible] July last under the observation and care of Dr. Robert H. Babcock of Chicago It was he who in April of 1902 first informed me that mine was a case of Stokes-Adams disease, although the original examination of me by Dr. Babcock had been made as early as October, 1899. Dr. Babcock informed me that he was inclined to make that diagnosis after mature consideration [illegible] n appearing in the *Zeitschrift für* [illegible] r the article on the Stokes-Adams [illegible] *utsches Archiv für Klinische Medicin,* [illegible]

Personally I have made a thorough study of my case, so far as a lay [illegible] d reported entirely sound by [illegible] s *that that report was correct,* and the policy was issued [illegible] One [illegible] tly at [illegible] se examinations such addi- [illegible] were also reported. When I [illegible] six months afterwards) my [illegible] was apparently well. It is now, and [illegible] The usual [illegible] e cold [illegible] y bed [illegible] d my [illegible] I have begun to gain since I resumed a general diet about four weeks ago. There is a marked systolic murmur over the aortic and mitral areas, both of which murmurs become very much less marked when heart action is normal. Careful auscultation reveals usually two small heart contractions of which the latter produces the radial pulse. The former (imperfect) contraction does not produce a pulse-wave either in carotids or in the radials. None of the ordinary secondary symptoms of valvular disease of the heart, such as dyspnœa, dropsy, cyanosis, &c, are present in my case.

Yours, &c,

——

DIAGNOSIS.

The severe form (Cases 2 to 6) presents such a clear-cut picture that there is no question as to the nature of the trouble The senile form is also very well marked. The post-febrile variety may be very severe but is as a rule more hopeful and recovery, as in Schuster's case, may follow after weeks of recurring attacks The toxic forms of bradycardia are sometimes associated with vertigo but rarely with syncope or epilepsy The tobacco bradycardia may sometimes cause alarm. I was consulted on Jan. 7th, 1896, by a man, aged 48 years, who said that he had had heart disease for three years. He had smoked and chewed from boyhood. He complained of irregular action of the heart and a dull aching sensation in the chest. He then had attacks in which the pulse fell to 45 and 48 and which caused him great alarm. He had transient vertigo but never syncope. There were no signs of heart disease. I urged him to stop using tobacco. Within three months the pulse-rate was above 70. I have seen him on several occasions since and he has remained quite well.

A difficulty may arise in the diagnosis of the neurotic cases in women or in young men. Dr. Edes's first case illustrates the intensity of this form. Aggravated neurasthenia may be associated with bradycardia and vertigo of which the following cases may be given in illustration.

CASE 13.—A man, aged 44 years, was admitted to the Johns Hopkins Hospital on Oct. 29th, 1899, complaining of pain in the epigastrium, headache, and of swaying of the body while walking. He had used tobacco to excess, both smoking and chewing. He used whisky in moderation. He had not had syphilis but had had gonorrhœa twice. He had led a very active athletic life. Six months before, after severe exertion and exposure [illegible] upwards from the thighs wl [illegible] uncomfortable He worried [illegible] so much difficulty in getting his breath that he thought he had heart disease and was going to die. He stopped work for a few days but on resuming he had a similar attack and complained of a peculiar swaying of the body which he could not control. The patient worked for two months but the swaying and pains in the crown of the head and in the epigastrium compelled him to give up. He was very nervous and complained of flushing, cold feet, and insomnia. He had lived a life of continued "high tension." He was a stout well-built man; the lips and the mucous membranes were of good colour; the tongue was slightly furred. The pupils were equal but not contracted; they reacted well to light and to accommodation. Well-marked dermatographia was present. There was some swaying on standing with the eyes closed and feet together. The pulse was of good volume and normal tension, regular in force and rhythm, but slow, being only 48 to the minute. The point of maximum cardiac impulse was neither visible nor palpable. The sounds were best heard in the fourth interspace nine and a half centimetres from the midsternal line; there was no thrill. The sounds were rather enfeebled at the apex and were clear and of normal relative intensity; they were clear at the base; the aortic second sound was slightly accentuated. There were no abortive beats. According to the patient's wife he had since childhood had an aversion to water, the drinking of which would cause him to have a "smothering" feeling at night. At the onset of the present illness the patient went to bed feeling perfectly well; he woke up in the night with a feeling of being smothered, so he got up and went outside. He was convinced that he was dying and after a time could not walk and had to crawl home. He was put to bed; he went to work as usual on the next morning. One week later he had a similar attack. His wife said that since the onset of the attacks he would often get up at night wringing his hands and in great fear of death, but was usually easily quieted. The patient improved very much after a short stay in the hospital, but the pulse was still slow, from 48 to 50 to the minute.

The following is a still more remarkable instance of a very slow pulse with nervous attacks.

CASE 14.—The patient, a man, aged 26 years, was seen on Oct. 4th, 1901, with Dr. Harry Thomas, complaining of attacks of nervous weakness. The family history was excellent. He had good health as a young man. In January, 1895, he fell about 20 feet, hit his back, and was severely hurt in the muscles of the back; no paralysis followed. He was in bed for three months on account of the pain in the back. This was his first year at college. He got well, except that on cold damp days his back would hurt him. His present trouble came on before the fall, in March, 1894. He had been feeling well and went to bed. In the morning he found that he was "giddy-headed" and everything in the room seemed to be turning round; he felt a little sick at the stomach. When he tried to get up he was very unsteady and if he moved suddenly he would fall; he had to support himself by chairs, &c. There were no ringing in the ears and no vomiting. He became nervous and went back to bed. The pulse sank to 42; there was no fever. The bowels were in good condition; he had a good appetite. He was in bed for three or four weeks. Every time he tried to stand he found that he was so weak that he had to go back to bed. If he did get up his heart would go from 80 to 100. He could not read on account of the headache that it caused. When he did get about he was weak. He improved slowly and in about six weeks was as usual. At the time of the first attack he was working on a farm and had had nothing to disturb him. The second attack was in about a year after his fall. Since then these attacks had recurred from eight to 12 months apart. They had all been of the same character, except that some were longer and some shorter. The shortest one was about three and a half weeks. This was in 1898. The last attack began on the afternoon of August 5th. He was taken with giddiness and vomiting and had to be taken home in a carriage and practically carried upstairs and put to bed. It was not weakness at first that kept him from walking but giddiness. The temperature was normal and remained so. On the next afternoon the pulse was 48. He was in bed for eight days and then went to his home 28 miles away with assistance. He had stayed more or less in bed every day since. The giddiness had lasted much longer in this attack than usual. He tried to go back to work a week before but was not strong enough. In going about the pulse increased to 93. The pulse when he was well was about 74 when he was going about. He was a healthy, robust-looking fellow. The pupils were active. The radials were soft; there was no sclerosis. The pulse was 80. The chest was rather long and narrow. The apex beat was in the fifth interspace, well inside the nipple line. There was no increase in the area of cardiac flatness. The aorta was not palpable in the sternal notch. The sounds at the apex and base were loud and clear; the aortic second sound was a little accentuated. In the carotids and the subclavians there was visible, possibly neurotic, throbbing. Marked and quick vaso-motor reaction was present.

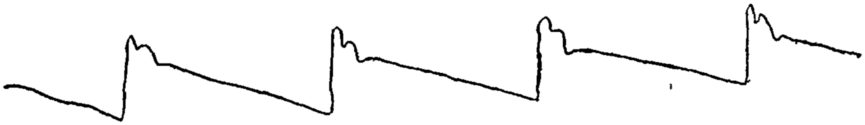
These are certainly very remarkable attacks. They rather suggest a form of migraine and yet the ears were normal and the patient had no ringing in the ears with the attacks. He gave one the impression of being an excessively nervous man. On a course of hydrotherapy he had improved very much. Dehio suggests the use of atropia to determine in a given case whether the bradycardia is due to changes in the heart itself or in the nervous centres. In normal persons small doses paralyse the peripheral ends of the vagi and the action of the heart is hastened. In old people, in chronic myocarditis, and in one case of Stokes-Adams disease Dehio states that this effect did not follow. I do not know if this observation has been confirmed.

CARDIO-VASCULAR FEATURES.

All of the patients except Case 1 with an acute post-febrile attack presented arterio-sclerosis; in Cases 5, 11, and 12 it was of moderate grade. In no case was the heart greatly enlarged. In Cases 2, 4, 5, and 10 there was a soft mitral systolic murmur; in Case 9 an aortic diastolic murmur was present. In Cases 4 and 5 the sounds were weak and muffled. In the only necropsy of the series (Case 2) the arteries were found to be sclerotic, the root of the aorta and the coronary arteries were calcified, and the left ventricle was hypertrophied. The condition is not associated with the ordinary forms of valvular lesions, as in a majority of the cases the valves are normal, the heart is not enlarged, and the sounds are clear. In Dr. Edes's series collected from the literature in 31 of the 35 cases in which a necropsy was held there was a definite statement as to the heart and arteries and in 26 there were sclerotic and myocardial changes. Certain special features may be considered.

True bradycardia.—One of the first lessons a student has to learn in the wards is that infrequent slow pulse and bradycardia are not the same and that with an infrequent pulse there may be a normal or an increased number of heart beats. In lesions of the mitral valve, in chronic myocarditis, and as a result of the action of digitalis, the radial pulse may be 50 or even 40 and the heart beats exactly double, the intervening small beat (often visible at the apex in thin-chested persons and audible as a faint systolic sound) not reaching the finger at the wrist. True bradycardia with heart beats and pulse beats of equal number occurred in most of the cases, only in Cases 5, 8, and 12 did it alternate with false bradycardia. In eight cases the bradycardia was a permanent condition; in one case the beats fell to 12 per minute; in Case 9 the slow pulse had been observed for 30 years, in Case 2 for six years, and in Case 6 for at least ten years. In Cases 1 and 2 the slow pulse was not permanent but only occurred during the attacks. In Dr. Hamburger's case with a heart-rate at 20 prior to a convulsive attack I counted intervals of 20, 30, and once 35 seconds in which there was no heart beat to be seen, heard, or felt. The pulse in true bradycardia is usually full, strong, and regular. This last feature is marked and is apt to deceive the inexperienced as it may be present with intervening abortive systoles—the "coupled rhythm." There may be a very strong pulse with an indistinct cardiac impulse and feeble sounds, or just the opposite. The infrequency in true bradycardia seems to be due to prolongation of the diastole; the systole as a rule is sharp and quick. The tracing which is here presented shows this very clearly. By far the best sphygmogram I have seen is the one here given which was taken by Dr. Wells of Chicago. It is a normal tracing, except in the extraordinary prolongation of the line of descent, the period of diastole.

False bradycardia.—Stokes noted in his patient that the pulse-rate and the heart-rate were not the same and that there were semi-beats of the heart. In three of my series these abortive beats were present. They may not be evident at the radials or in the carotids where the pulsations may be in orderly sequence and of exactly equal size—so that at the wrist there is no indication whatever of arrhythmia; even the sphygmographic tracing may not show the interpolated beats. They may sometimes be seen and felt at the apex as in Case 5; more often they may be heard with distinctness. The number of abortive systoles varies; usually they are alternate and in orderly sequence, so that with a pulse of 40 at the wrist 80 heart beats may be seen and 80 first sounds may be heard—the "coupled rhythm" In the severe attacks with very infrequent pulse there may be a number of abortive beats In Case 5 in which this feature was studied with great care there were remarkable variations On one occasion, with a pulse rate at the wrist of 12, the heart beats were 100, on another they were 143 On May 26th the pulse was 19 to the minute at the wrist, with 74 palpable, visible, and audible cardiac beats On the 29th the pulse rate and heart-rate were the same (28), no intervening beats could be seen, but on auscultation there were feeble, only just audible, systolic sounds intervening between the forcible thumping pulsations which shook the whole chest



Pulse-tracing of the patient whose description of his own case is given above Pulse-rate at 40

The question has been raised whether in all cases there are not these abortive beats, too feeble to be seen, felt, or heard Case 5 was a very favourable one in which to study this problem All the abortive systoles were usually visible on the thin chest wall and palpable One day with the pulse at 28 and the same apparently at the heart and the wrist and without any visible or palpable abortive systoles such as were usually present, on auscultation one could hear distinctly soft systolic sounds intervening between the loud booming shocks In other cases I have listened with the greatest care but in vain for these abortive sounds

The "heart block," or independent auricular systole without corresponding ventricular contractions —Stokes noted on the readmission of his patient a new symptom—a remarkable pulsation in the right jugular vein, more than double the rate of the ventricular contractions This feature has been studied by Chauveau, by Quincke, by His, jun, and others, who are of opinion that the jugular pulsations correspond to independent auricular contractions which are not propagated to the ventricles—a state of "heart-block," as Gaskell terms it In Case 5 the jugular pulsations never corresponded in number with the carotid pulsations or with the total number of ventricular beats Cardiac, radial, and jugular tracings were taken simultaneously, from which, unfortunately, nothing very definite could be determined

Jacquet has recently called in question the existence of these independent auricular contractions,[8] the existence of which his tracings do not support It is quite possible that there are ventricular contractions too feeble to be heard and too feeble to open the sigmoid valves, yet which might in a dilated heart cause a pulse wave in the right jugular vein In Case 5 as a rule the interpolated beats were palpable, visible, and audible, but they continued to be *heard* after they had ceased to be felt or seen, and still feebler contractions might cause no sound and yet transmit a wave to the veins through an insufficient tricuspid valve We cannot dismiss the question of independent auricular contractions as settled In

nite jugular pulsations
s of systole with com

Cardiac arrest —This phenomenon is one of the most remarkable witnessed at the bedside In the case just referred to the apparent stoppage always preceded the slight convulsive attack The eyes were set, the face was flushed at first, then pale, and the patient appeared to be in the article of death. In such circumstances to wait 35 seconds, watch in hand, without a heart beat seems like the final "count-out", but this man, after scores of such attacks, recovered sufficiently to go to his home A precisely similar condition is met with in some cases of angina pectoris It always suggests to me the heart state of fibrillary contraction produced experimentally by the Kronecker puncture

Vaso-motor changes —As in angina pectoris the vaso motor system is profoundly involved in the severe attacks, as shown by the pallor, the sweating, and the vomiting, and in some cases by the marked paræsthesia, the numbness, and the tingling

NERVOUS FEATURES.

It is for these the patient seeks relief, naturally much alarmed Four forms of attack occur —

Vertigo —While walking in the streets or engaged in conversation the patient feels giddy and staggers or may fall unless he catches hold of something As in Case 2, the attack may be of great severity and very distressing, incapacitating the patient The attacks may precede for years the onset of severer forms In very old men with a permanent slow pulse this may be the only manifestation It is a well-recognised and common symptom of arterio sclerosis

Syncope —Much more alarming are the fainting attacks with complete loss of consciousness. Without warning the patient becomes pale and may fall instantly in a deep faint, with feeble, imperceptible pulse and the general features of cardio-vascular collapse. The respirations are shallow, a clammy sweat breaks out, and in severe attacks death may seem imminent, indeed, the patient may pass away without recovering consciousness As a rule the attack does not last more than a few minutes Many attacks may occur in a day and, as in Case 2, they may alternate with vertigo They may resemble in character *petit mal* Syncope is the most frequent of the severe nervous symptoms and occurred in eight of my cases

Pseudo apoplexy —The patient falls in a deep coma, with loud stertorous breathing, deeply congested face, and all the features of an apoplectic stroke Both Adams and Stokes describe the condition most accurately and the latter comments on the remarkable circumstance that there is no consecutive paralysis, as after an ordinary stroke There are rarely convulsive movements and in four or five minutes consciousness is restored and the patient may get up and go about his work (Case 6) An extraordinary feature is the frequency of the attacks as noted by Adams and Stokes In Case 6 they had recurred for many years and had been associated with transient attacks of motor aphasia, such as are met with not infrequently in advanced arterio-sclerosis.

Epileptic seizures —As mentioned, the transient vertigo and syncope may resemble *petit mal* The convulsive attacks are either slight spasms of the muscles of the face and hands with the loss of consciousness, as in Case 5, or more rarely they may be more general, resembling true epilepsy In Case 5 and in Dr Hamburger's case the convulsive attacks were very frequent In the latter we could tell at once when the attack was coming on The pulse would stop for 20 or more seconds, the face flushed, the breath was held, the eyes rolled up and twitching of the face and hands began Sometimes the attacks may not last for more than a few seconds and the patient may go on with a conversation, even a 100 or more of such attacks may occur in a day.

PULMONARY FEATURES

The cases present the respiratory symptoms so often met with in chronic myocarditis Attacks of cardiac asthma are common, occurring chiefly at night (Case 9) These may be the features of angina sine dolore, the distress, the pallor, the sweating, the shortness of breath, or the state called by Goodhart acute emphysema, with universal wheezing, the *Lungen-starheit* and *Lungenschwellung* of von Basch—which, I take it, is nothing more than acute œdema of the lungs Cheyne Stokes breathing is more common and was met with in four cases of my series In the pseudo-apoplectic attacks the stertor, with deep laboured respiration and expiratory puffing of the cheeks, may have all the intensity of the genuine stroke Prior to the attacks of epilepsy there may be transient arrest of respiration with flushing of the face

PATHOLOGY

It is by no means easy to discuss intelligently the pathology of these remarkable attacks We have two great groups of bradycardia—the one associated with lesions in the heart itself, the other with disturbances in the nervous respiration-rate was from 20 to 24 per minute. The tongue was furred and there were complete anorexia, slight headache, a good deal of pain at the back of the neck, and marked mental depression. After the first few days there was some diarrhœa, two or three loose motions being passed daily. On Jan. 1st the blood was examined and the Widal reaction was found to be positive (with a dilution of 1 in 30 complete clumping occurred at the end of half an hour). At this time the disease was regarded as in all probability typhoid fever, especially as the symptoms and the course of the temperature were exceedingly similar to those which had been present at a corresponding period of the illness of another nurse who had died from undoubted enteric fever only a week or two previously. There were, however, no distension of the abdomen, no evidence of enlargement of the spleen, no bronchitis, and no appearance of spots. The symptoms now continued with very little alteration for several weeks, except that the diarrhœa gradually subsided. The temperature rose every evening with great regularity, for the first four days to 104°, then for about a fortnight to 103°, and afterwards to 101° or 102°; it was always normal, or very nearly normal, in the morning, except—as already mentioned—for the first few days. There was never any rigor or shivering. This persistently intermittent type of fever, together with the absence of many of the ordinary symptoms of typhoid fever, gradually rendered the diagnosis less and less probable; but although repeated careful examinations were made no other cause for the fever could be found until at last attention was directed to the condition of the mouth. After the patient had been in bed a week or two she began to complain of dryness and soreness of the lips, gums, and front of the mouth. At first these symptoms were attributed merely to the fever and to the general condition, but as some pyorrhœa alveolaris was found to be present various antiseptic lotions were employed and shortly afterwards the evening rise of temperature began to be distinctly less marked. It was only, however, the long and regular persistence of the fever and the utter inability to find any other cause for it that at last led to the suspicion that the condition of the gums might actually account for the illness. Mr. Roughton was therefore asked to see the patient and as he found that pus exuded on pressure from the sockets of both the upper and lower incisor and canine teeth, particularly around the upper lateral incisors, he advised the extraction of these two teeth. This was done on Jan. 27th and there was a relatively considerable escape of pus afterwards from the sockets; in addition a thorough antiseptic treatment was applied to the gums generally, chiefly by a 1 in 80 solution of carbolic acid. The effect was immediate. The highest temperature on Jan. 27th was 101·4°, next day it only reached 99·8°, and never subsequently rose to 99°. Convalescence was rapid and no special precautions were taken in regard to diet, solid food being given freely as soon as the patient wished for it. She has remained quite well ever since and the pyorrhœa alveolaris has been practically cured by the application of listerine and of a solution of hydrogen peroxide to the gums and teeth and by filling the pockets between the gums and teeth with powdered sulphate of copper. Three more teeth had, however, to be extracted owing to their becoming very loose. On Feb. 10th the blood was again examined and the Widal reaction was found to be negative (with a dilution of 1 in 30 most of the bacilli remained active at the end of half an hour, although a few clumps were seen).

---

[8] Deutsches Archiv für Klinische Medicin, Band lxxii.

In some lectures[1] delivered at the Medical Graduates' College and Polyclinic one of us drew attention to morbid conditions of the mouth as a source of systemic infection. Although not susceptible of logical proof there seems to be little doubt but that the case now recorded is an example of the effects of toxic absorption from suppurating gums. The indefinite nature of the febrile condition, coupled with its rapid disappearance as soon as the gums were adequately treated, seems to point very distinctly to the true nature of the case. The close resemblance of the symptoms in this case to those of typhoid fever is most interesting and suggests to the physician the advisability of carefully examining the condition of the mouth in all obscure febrile conditions and the importance of remembering that the mouth is not only an index of the condition of the alimentary canal, but may be really the *fons et origo mali*. Previous cases have been recorded of a positive Widal reaction in septicæmic and sapræmic conditions.

NOTE ON THE TREATMENT OF CHOREA BY ASPIRIN.

BY R. T. WILLIAMSON, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE ANCOATS HOSPITAL, MANCHESTER; ASSISTANT LECTURER ON MEDICINE AT OWENS COLLEGE; AND ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, MANCHESTER.

I HAVE recently endeavoured to ascertain whether the course of chorea minor can be influenced by treatment with aspirin. I have given the drug in 35 consecutive cases of chorea, in all of which the subjects were out-patients at the Ancoats Hospital and the Manchester Royal Infirmary. They were kept away from school but were not confined to bed. The favourable results obtained cannot therefore be attributed to the influence of rest in bed.

It is not without considerable hesitation that I have ventured to write this note on the treatment of chorea, since the disease is one which has usually a tendency to terminate in recovery in course of time, apart from any medical treatment. In the mild forms of the disease recovery may occur in from six to ten weeks, whilst in other cases the choreic movements may persist for many months, or even a year, or longer. Mild cases will recover without drug treatment. In severe cases we cannot immediately arrest the disease by aspirin or by any drug or form of treatment. When steady and progressive improvement follows medical treatment usually one or two weeks, often a longer time, must elapse before recovery is complete. Bearing these facts in mind the necessity for great caution in drawing conclusions as to the action of drugs will be evident. Notwithstanding these difficulties I believe that aspirin has a distinct beneficial effect in severe forms of chorea.

In the mildest forms of chorea good results often follow treatment by various drugs and may occur even when no drugs are given. In these very mild forms I have seen decided improvement in cases which I have treated simply with five minims of peppermint water three times a day or with very minute doses of quinine (one-quarter of a grain). Hence, though my mild cases have done well on aspirin, I cannot say that the result was due to the drug and that they would not have done well without it, but in the severe and persistent cases I believe that aspirin is of distinct service in diminishing the duration of the affection. Though the drug does not immediately check the choreic movements its administration is usually followed by distinct improvement in six or seven days after a dose of 10 or 15 grains four times a day has been reached. This improvement steadily continues until complete recovery occurs.

All of the 35 out-patients improved when treated with aspirin; the improvement was progressive and complete recovery occurred. When the patient was able to take aspirin well it was never necessary to resort to other drugs because improvement did not occur under the administration of aspirin. Further, I had no necessity to send any of the patients to bed for rest treatment. Though these general statements are in favour of the drug they will not convince readers of THE LANCET of its value and I am aware that I cannot put forward any *conclusive proofs* thereof. To furnish such conclusive proof of the curative action of aspirin it would be necessary to publish the results of treatment in two large series of cases of chorea, the cases in one series being treated with aspirin with better results than those obtained in the second series without the aspirin treatment. All other conditions should, of course, be the same in the two series. It is scarcely necessary to add that such series of observations are for many reasons very difficult to obtain. What has impressed me, however, so much in favour of aspirin is the steady and marked improvement which has often followed its use in severe cases of long duration which have resisted other drugs and methods of treatment. In cases of long duration and in recurring attacks the patients' friends have, on several occasions, been much impressed with the value of the aspirin and on the recurrence of choreic movements at a later date have reminded me of the benefit derived from the drug in the previous attack. I am aware that such statements by the patients' friends are by no means conclusive evidence of the value of any drug; nevertheless they are worthy of mention.

---

[1] Roughton: On Some Morbid Conditions of the Mouth, THE LANCET, Sept. 27th (p. 847) and Oct. 18th (p. 1029) and 25th (p. 1108), 1902.

As regards the administration of the drug I have usually commenced with 10 grains as a powder twice a day in children over seven years of age and rapidly increased up to 10 or 15 grains (according to age) four times a day. In children under seven years of age smaller doses will be necessary. It is, of course, important to watch for toxic symptoms and to diminish the dose or to discontinue the drug if these occur. Toxic symptoms similar to those caused by salicylates (noises in the ears, &c.) do not often occur and most children take the large doses just mentioned without any ill-effects, but occasionally the drug causes gastric irritation or vomiting even in small doses of five grains. These symptoms I have not infrequently noticed in patients receiving the drug from the out-patient room at the Manchester Royal Infirmary but very rarely in patients at the Ancoats Hospital. It is probable that the vomiting is due to some impurity of the drug or to some idiosyncrasy of the patient. It is important that no alkali should be taken just after the aspirin, otherwise the drug is very liable to decompose in the stomach and to produce gastric symptoms. I usually give the powders in water to which a drop of lemon-juice has been added. If in spite of these precautions gastric symptoms and vomiting occur the drug should be discontinued. I have been obliged to discontinue the drug permanently in a few cases on account of sickness, but had not to do so in any of the 35 cases here under consideration. I believe that it is only when the doses already mentioned can be taken well that the drug is likely to be of service. The following are brief abstracts of notes of eight out of the 35 cases.

CASE 1.—The patient was a girl, aged 14 years, who had had two previous attacks of chorea. The present attack had been of four months' duration. The patient had been previously treated as an in-patient (with rest in bed) at a large hospital with very little effect. Aspirin was given (15 grains three times a day); steady and marked improvement occurred. At the end of 24 days there was complete recovery with no recurrence of the symptoms.

CASE 2.—This was a case of chorea of six months' duration in a girl, aged 11 years. She was treated with small doses of liquor arsenicalis for three weeks without any effect. Aspirin was then given. Steady and marked improvement occurred and the patient ceased to attend the hospital. Three months later choreic movements returned. After this second attack of chorea had continued for six weeks the patient was brought to the out-patient room by her mother who reminded me of the rapid improvement which had followed the use of the powders (of aspirin) in the first attack. Aspirin was given, 10 grains three times a day and the dose was increased to 15 grains four times a day. In six days there was distinct improvement; three days later the improvement was more marked and when seen 12 days after the commencement of the aspirin treatment (and seven days after the dose of 15 grains four times a day had been reached) the patient was quite well and the choreic movements had entirely ceased.

CASE 3.—The patient, a girl, aged 12 years, had had repeated attacks of chorea for four years with occasional short intermissions of three or four weeks' duration. She was taken to the out-patient room of the Ancoats Hospital suffering from a severe attack of chorea which had persisted for three months. Aspirin was given with good results and the chorea rapidly subsided. For more than two months she remained quite well. The aspirin was discontinued. Early in 1903 the choreic movements returned and a severe attack of the affection developed. The girl had previously been treated as a hospital patient, but in order that she might have the same powders (of aspirin), and as she was not so poor as most hospital patients, her mother brought her to see me privately. The mother reminded me of the benefit which had been derived from the aspirin previously and requested that her daughter might again have the same treatment, as no other drug which had been tried in her numerous attacks had given her so much relief. Aspirin (10 grains three times a day) was given on Feb. 27th. On March 9th there was a little improvement and the dose was increased to 15 grains four times a day. On March 16th the improvement was decided and on the 28th the chorea was slight. On April 3rd the patient was practically well and she has remained quite well since that date.

CASE 4.—The patient was a girl, aged eight years. The onset of chorea happened about Christmas, 1902, and the symptoms gradually increased until Feb. 5th, 1903, when aspirin was given (10 grains three times a day) and improvement occurred. On Feb. 12th she was much better. The improvement was so marked that she discontinued all treatment. In a short time the choreic movements became much worse and she returned to the out-patient room for further treatment. On the 23rd aspirin (10 grains four times a day) was given. Improvement occurred rapidly and on March 2nd the chorea had entirely disappeared.

CASE 5.—This patient, a girl aged 14 years, had had chorea for two weeks. The movements were very violent. On April 8th aspirin was given (15 grains four times a day). On the 11th there was considerable improvement. On the 15th, one week after the drug was commenced, the choreic movements had almost ceased and on the 29th she was practically well.

CASE 6.—The patient, a girl, aged 13 years, was seen soon after the onset of the chorea. Aspirin was given (10 grains three times a day) and slight improvement occurred but the drug caused sickness and had to be discontinued. Liquor arsenicalis was given in small doses for five days but the choreic movements increased. For three days she was given aspirin but as sickness occurred it was again discontinued and for three days liquor arsenicalis was given. Then on Feb. 15th aspirin was given (15 grains four times a day). The patient was now able to continue this dose and decided improvement was noted on the 26th (five weeks after the onset of the disease). On March 2nd very little choreic movement could be detected. On the 16th the chorea had entirely disappeared.

CASE 7.—The patient was a girl, aged 12 years. The onset of the illness occurred at the end of May, 1903. The patient was treated at a large hospital and kept in bed for two weeks but no improvement resulted. I first saw the case one month after the onset of the affection. The choreic movements were then very marked. Aspirin was given on June 29th (10 grains twice a day) and was increased up to four times a day on July 1st. When seen on the next day the condition was much the same but on the 6th there was marked improvement On the 9th the patient was practically well and by the 13th not the slightest trace of choreic movement could be detected.

CASE 8.—The patient was a boy, aged 15 years. There was a history of chorea 12 months before. The present attack had been of six weeks' duration and no improvement had taken place up to the time the aspirin was given on July 5th (10 grains four times a day). On the 9th and 13th only very slight improvement was noticed, but it was found that the aspirin had not been taken very regularly. The necessity for regularity was pointed out and the drug was continued. On the 20th the boy was practically well.

Amongst these 35 out-patients treated with aspirin there were cases of very long duration in which the symptoms persisted unchanged until this drug was given; decided improvement first occurred under treatment with aspirin and complete recovery followed. Often other methods of treatment had been tried without effect. Also in some severe cases of short duration—i.e., cases seen soon after the onset of the disease—improvement occurred rapidly when the patient was brought well under the influence of aspirin and complete recovery soon followed. From these and other facts already mentioned I do not think that the favourable results of treatment by aspirin can be attributed to lucky coincidences.

Though aspirin cannot be regarded as a specific for chorea, the results obtained by its administration are so favourable as to indicate the great probability of a beneficial action of the drug and it appears desirable that further observations should be made. It is only by very numerous observations that the beneficial action of drug treatment can be established in any affection which has a natural tendency to recovery.

Manchester.

AMPUTATION OF THE LEG UNDER HYPNOTISM.

BY FRANK G. ALDRICH, L.S.A.

IN the belief that the following case will prove of interest to the medical profession I venture to record it. The interest taken in hypnotism in this country is very small and the value of its therapeutic action in suitable is not appreciated. From an experience lasting lungs, liver, kidneys, and spleen were normal and there was not the slightest trace of organic nervous disease. The patient is a man of iron nerves, as may be gathered from the fact that he is a rifle shot of the first order and has won many prizes for shooting. He had suffered from occasional attacks of flatulent dyspepsia and it was to one of these attacks with its concomitant cardiac pain from distension of the diaphragm that I was indebted for an opportunity of observing a case of what I believe to be absolutely physiological bradycardia. I placed the patient on a careful dietary and a course of stomachic bitters with pepsine and the præcordial distress rapidly disappeared and, so far as I am aware, has not returned. He was under my immediate supervision for upwards of six months and I have heard from him at intervals since. The last Indian mail brought me a letter from him informing me that at the time of writing he was in excellent health and free from the præcordial discomfort but that the pulse-rate remains unaltered, so as the patient came under my observation nearly 18 months ago the condition may be safely considered to be permanent.

The case is, of course, not unique, as in addition to the case of Napoleon mentioned above, Roux, Sir William Broadbent and other observers have recorded somewhat similar ones, but it is, I think, sufficiently uncommon, especially in military practice, to merit being placed on record.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CONCERNING THE NATURE OF THE GREEN PIGMENTATION OF THE TISSUES IN CHLOROMA.

BY EDGAR G. TREVITHICK, M.D. CANTAB.,
PHYSICIAN TO THE CHELTENHAM GENERAL HOSPITAL.

IN describing a case of chloroma in THE LANCET of July 18th, 1903, p. 158, I stated that the brilliant green pigmentation of the affected organs faded rapidly after their removal from the body and that I had been unable to find any reagent that would bring back the colour. I now wish to record the observation that when such organs are treated with a solution of peroxide of hydrogen the green colouration becomes quickly restored. When removed from the peroxide bath the colour again fades away, but if after the tissues have been thus a second time bleached by exposure to air they be once more immersed in the peroxide solution the green colouration reappears.

I send this additional note on the case in the hope that the facts herein stated may enable those who are well versed in the subject of pigmentations to form some opinion as to the nature of the substance responsible for the manifestations described.

The kidneys, the ovaries, the uterus, and certain other tissues from this case had rested in formalin solution for rather more than two months and had entirely lost their greenness. When, however, one of the kidneys was placed in the peroxide solution the distribution of the original green pigmentation became, in the course of a few minutes, most faithfully reproduced. The whole of the subcapsular layer quickly regained its green colour and, in addition, all the small green islands originally described as occurring in the medullary portion of the gland again came into evidence.

Cheltenham.

HERNIOTOMY UNDER LOCAL ANÆSTHESIA.

BY MARCUS MARWOOD BOWLAN, M.B., B.S. DURH.,
MEDICAL SUPERINTENDENT, ST. GEORGE'S-IN-THE-EAST INFIRMARY.

THE interesting lecture on Local Analgesia by Mr. A. E. J. Barker published in THE LANCET of July 25th, p. 203, leads me to submit the following brief note of a case of herniotomy under local anæsthesia.

The patient, who was a feeble woman, 77 years of age, vomited on June 12th, 1903, and this continued until the next day (the 13th). When she came under my care I found her to be suffering from a right femoral hernia with absence of impulse on coughing. The vomit consisted of the contents of the upper intestine. The breath had a fæcal smell. The specific gravity of the urine was 1023, it was acid, and contained a trace of albumin. On the same afternoon 40 minims of a 1 per cent. solution of beta eucaine were injected under the skin of the area selected for incision and a quarter of an hour later the incision was made, the patient feeling no pain. About 20 minims more of the same solution were dropped into the wound during the dissection so that only one drachm of the 1 per cent. solution of eucaine was used. On opening the sac the gut exposed was found to be deeply congested and some blood-stained fluid escaped. However, on examining the crural ring with the finger the hernia slipped back through it so that the hernia knife had not to be used. The sac was separated and tied with catgut. The patient retched a little during the night and had occasional hiccough, feeble pulse, and dryish tongue, but these symptoms quickly yielded to whisky and strychnine. Flatus was passed per anum on the next day but the bowels were only moved by an aperient four days later. The wound was apparently healed on the fifth day when it was dressed and the sutures were removed, but when it was dressed again on the 24th a small subcutaneous abscess had formed and this was drained with gauze. Possibly the eucaine solution was not quite sterile, though her temperature was never above 98 8° F. By July 21st the wound was quite sound and a few days later the patient was up and about but, of course, wearing a truss.

Before, and for a few days after, the operation the condition of the patient was serious, the heart's action being feeble and irregular, and it is a question whether a general anæsthetic would not have added sufficient (drug) "shock" to have proved fatal.

WESTMINSTER HOSPITAL.

A CASE OF ŒSOPHAGOTOMY FOR THE REMOVAL OF A PORTION OF AN UPPER TOOTH-PLATE.

(Under the care of Mr. WALTER G. SPENCER.)

FOR the notes of the case we are indebted to Mr. G. Brittan Gill, house surgeon.

A female, aged 37 years, broke her upper tooth-plate but continued to make use of the two portions. On June 12th last, whilst at breakfast, the smaller fragment containing a bicuspid and two molars was carried into the pharynx. In trying to remove it the patient pushed it downwards out of reach. She was then seen by Dr. M. Sharman of Rickmansworth who made repeated attempts to extract the plate, in which he was assisted by Dr. E. A. Peters. The plate was several times grasped by forceps but could not be drawn upwards. For some days the patient refused but ultimately consented to go to hospital. Meanwhile she had marked dysphagia and pain in flexing the head but no dyspnœa. A skiagram showed the plate to be situated about the level of the seventh cervical and first dorsal vertebræ, a short distance below the cricoid cartilage.

On June 16th—i.e., on the fifth day from the accident—the plate was removed by Mr. W. G. Spencer, assisted by Mr. E. P. Paton, Dr. Sharman and Dr. Peters being present. The patient was anæsthetised without difficulty and then a fulness could be detected in the neck low down on the left side, but there was also a considerable enlargement of the thyroid gland. A No. 18 bougie was passed without meeting with any marked obstruction. An incision was made along the inner border of the left sterno-mastoid from the level of the thyroid cartilage for an inch or so in front of the manubrium The sterno-mastoid having been drawn outwards the jugular vein and carotid artery with the sterno-hyoid and sterno thyroid muscles as well as the recurrent laryngeal nerve were retracted inwards The œsophagus was thus exposed a short distance below the cricoid cartilage and the plate could be felt through the wall The plate was easily extracted, the œsophageal wall proving friable from septic inflammation, and tearing a little beyond the place actually cut through The wall would not hold sutures, so two drainage tubes were placed with their ends close to the opening and the rest of the wound was filled with iodoform gauze The patient was placed in bed without a pillow and with the foot of the bed raised She had been very excited before the operation but after it she was most amenable She was fed entirely by the rectum for the ensuing week, during which muco pus escaped freely from the wound On the fourth day there was found a tendency for the discharge to collect in the upper part of the wound, whilst all sign of inflammation spreading downwards was absent therefore the patient's position was changed and her shoulders were well raised

The pulse immediately after the operation was 130, on the next day it was 120 after which it subsided to the normal. The temperature on the first day reached 100° F and the respirations were 28, after which there was no elevation The patient's voice was hoarse for a few days and then it cleared Some water given her to drink on the eighth day nearly all flowed out by the wound On the tenth day egg with milk was for the most part swallowed On the fifteenth day she could swallow minced meat. She went home on July 6th, little more than three weeks from the accident and able to take full diet, the wound being represented by a small patch of granulations without any leakage from the œsophagus

Remarks by Mr SPENCER —Œsophagotomy for the removal of an impacted tooth plate has been in the past a most dangerous operation. After the skilful removal of the plate patients have succumbed to septic inflammation spreading to the mediastina and the lungs This has especially been the case when the superficial wound has been sewn up Many such cases are easily relieved by extracting the plate by means of a horsehair probang, coin catcher, or forceps Here this proved impossible Considerable fragments may pass and escape per anum A remarkable specimen preserved in the Museum of the Royal College of Surgeons of England is depicted by Dr F S Palmer in THE LANCET of Dec 10th, 1881 p 997 The plate was discharged about 17 hours after being pushed down the œsophagus The only alternative line of treatment which suggests itself is the passage of a straight tube and the breaking up the fragment with a lithotrite In this patient the cervical vertebræ projected forwards, so that even a soft bougie required the aid of the finger to pass, and thus no straight œsophagoscope could have been inserted Moreover, on the fifth day of impaction the œsophageal wall was anticipated to be in the friable condition found at the operation In operating the vessels were drawn inwards instead of outwards because the patient had a somewhat enlarged thyroid gland and numerous veins running between the lateral lobe and the jugular might otherwise have been met with Probably the sympathetic nerve was irritated, hence the rapidity of the pulse after the operation The patient's temporary hoarseness was doubtless the result of stretching the recurrent laryngeal nerve whilst drawing it aside

The experience of Mr H T Butlin in the removal of œsophageal pouches leads him to advise the application of sutures to the œsophagus only and to treat the rest of the wound by the open method In the present instance the fact that the wound soon healed shows that the open method does not give rise to any marked delay

---

SUSSEX COUNTY HOSPITAL

A CASE OF FRACTURE OF THE BASE OF THE SKULL WITH EXTRADURAL HÆMORRHAGE CAUSING COMPRESSION, TREPHINING

(Under the care of Mr R. F JOWERS)

A CABDRIVER, aged 39 years, was admitted to the Sussex County Hospital on March 3rd, 1903 having had a "fit" and fallen on to the paving of his stable He was said to be a heavy drinker and had been drinking that morning He had had one fit previously about three months before admission After the accident he walked to the hospital and while in the waiting room is said to have had another fit At any rate, he became unconscious and slipped from his chair on to the floor, in which position he was first seen by the assistant house surgeon who noticed that the pupils were unequal (the left being the larger) and that there was bleeding from the right ear This was dressed and the patient was sent into the ward When seen by Mr Jowers about two hours later he was lying quietly in bed in a semi conscious condition He was aware of being spoken to but gave incoherent muttering answers and resisted any attempt to see his pupils No fracture of the vault could be detected His temperature was 99 2° F and his pulse was 60 The right ear was ordered to be syringed twice daily and an emulsion of iodoform dropped in On the 4th the patient had had a restless night, he was delirious tremulous and picked at the bedclothes His condition suggested delirium tremens or some form of cerebral irritation He vigorously resisted any attempt to examine his pupils His temperature was 99 2° and his pulse was 74 On the 5th he had another restless night but was conscious in the morning He talked quite sensibly and said that he felt better His temperature was 98 2° and his pulse was 62 At 2 P M when seen by Mr Jowers he was quite unconscious There was well marked rigidity of the left arm and leg The right pupil was widely dilated and inactive and there was ptosis of the right eyelid The knee jerks were exaggerated and Babinsky's sign was present The temperature had risen to 100 8 and the pulse to 110 A consultation was held with Mr W Furner and Mr T J Verrall, who were in the ward at the moment and it was decided that if no improvement took place in a few hours he should be operated upon At 5 P M the rigidity had passed off and had been replaced by paralysis of the left arm and leg He was sweating profusely and breathing stertorously The temperature had risen still further and at 6 P M had reached 103°

The theatre being in use at the time operation was postponed till 9 P M, when, the head having been shaved, Mr Jowers turned down a semilunar flap and trephined over the middle meningeal artery, the opening being enlarged with bone forceps A large and thick extradural clot was exposed extending backwards further than the finger could reach and downwards towards the base of the skull. After removal of the clot with the finger and a scoop a large cavity was left between the skull and the dura mater, the brain showing no tendency to expand while the patient was on the table The cavity was gently irrigated with saline solution and the flap was sutured a drainage tube being brought out at each angle of the wound With the exception of the vessels in the flap and a small one in the bone which was stopped with Horsley's wax no bleeding was seen The patient had a good night and was quite conscious the next morning He could move his left arm and leg freely The right pupil, though less dilated still remained larger than the left, but now reacted to light There were some ptosis and paresis of the inferior rectus This and the other signs of paralysis of the third nerve entirely passed off in the course of the next few days He was very deaf in the right ear and could only hear a watch ticking on contact. A slight discharge of pus from one edge of the flap took place ten days later, but with this exception his recovery was uninterrupted A few days after operation the right ear was examined with the speculum which it had been impossible to do before There was a small blood clot adherent to the membrana tympani and partially obscuring it. By the time he left the hospital on April 29th his hearing had considerably improved and on examination no opening could be seen in the membrana tympani He has since been seen driving his cab

Remarks by Mr JOWERS —The difficulty at the time was to explain the onset of compression symptoms some 50 hours after the accident. It subsequently transpired that during the night previous to operation he struggled violently with the attendant in an endeavour to get out of bed The probability is that a hæmorrhage which had taken place in connexion with the fracture of the base and had become arrested was re started by his struggle and extended upwards till the whole hemisphere was compressed The exact source of the bleeding is uncertain Probably the fracture passed through the foramen spinosum, tearing the middle meningeal artery From the trephine opening the base could not be thoroughly seen and as no bleeding occurred there was no object in enlarging the opening so as to search for the fracture. In the few cases of compression from hæmorrhage I have met with the symptoms have been marked within a few hours of the accident. As the fact of his struggle with the attendant was not ascertained until the day after operation the explanation of the delayed symptoms due to compression was not apparent. The outlook in a heavy drinker with a fractured base was not encouraging, but operation seemed to offer the only chance of life.

Reviews and Notices of Books.

Social Origins. By ANDREW LANG, M.A., LL.D. *Primal Law.* By J. J. ATKINSON. London, New York, and Bombay: Longmans, Green, and Co. 1903. Pp. xi., 311. Price 10*s*. 6*d*. net.

THIS volume contains two distinct books which from a literary point of view might advantageously have been published separately. The introduction is written by Mr. Andrew Lang in his usual pleasing and playful manner which serves equally well to point the moral of a fairy tale or to illuminate the humour of an abstruse point of scientific interest. The manuscript of "Primal Law" was sent to Mr. Lang at the dying request of his cousin, James Jasper Atkinson, who had spent the greater part of his life in the New Caledonian Archipelago and who as a result of his observations discovered what he conceived to be the "primal law" which was the origin of morality as regards the family. Mr. Lang has very judiciously given to Mr. Atkinson's manuscript the last cares which, it is much to be regretted, the author himself was unable to carry out; he has also taken the opportunity to review the present state of the discussion as to the beginnings of the rules relating to marriages amongst savages. In so doing he occupies the greater part of the volume and what he says should prove of interest to all such as do not wish to take the subject too seriously, but desire rather to know something about the questions in dispute amongst serious anthropologists. To the German student an allusion, and one without an accurate reference, to the work of Thomas Haynes Bailey may prove a little embarrassing, but as a general rule exact references are given to the authorities quoted.

Mr. Atkinson's work is devoted to an explanation of his theory of the development of the social conditions of man in regard to family life, and he attempts to trace this development back to the condition of man when he was still in the brutal stage. From this it may be easily judged that the work is an ambitious one and when it is mentioned that the question is dealt with in eight short chapters and occupies little more than 80 pages it need hardly be added that the argument is presented in a somewhat condensed form. Mr. Atkinson held the Darwinian faith that "man is certainly descended from some ape-like creature" and, to use his own words, from this hypothesis he proceeds to treat of a "conjectural series of events in the Ascent of Man, events which involve a state of the intersexual relationships amidst our primitive ancestors identical with that portrayed in the 'Descent of Man.'" The essay in the course of the argument tends to confirm Darwin's ideas as to unity of origin. Mr. Atkinson suggests that the male ape-like ancestor of man was an unsocial creature largely imbued with fierce sexual jealousy—a solitary being save for association with one or more wives and female children. The young males of his and of similar families were rigidly exiled and these outcasts formed bands which ultimately became sufficiently strong to wrench both wives and lives from the paternal tyrants. There was ceaseless war between the patriarchs and the young males, for there was no special pairing season as in the case of the lower animals. As time went on it is assumed that the longevity of the race increased and this change entailed a more prolonged period of infancy, and then at length the dawn of brighter social conditions was brought about through maternal love. However caused, separation between the mother and her son was far more severely felt than it was by any other animal, and at each renewed banishment her feelings were increasingly outraged, her attempts to retain her youngest son grew stronger, and meanwhile the patriarchal fire of desire became quenched and his numerous daughters overtaxed his virile powers. In such circumstances a young male may have been permitted to live in his father's domestic circle, for at last, "given some such rather exceptional situation where an opportunity in superlative mother-love wrested with a for once satiated paternal appetite in desire, we may here discern a possible key to the sociological problem which occupies us and which consisted in a conjunction within one group of two adult males."

It is assumed that the junior male would be allowed to remain only on condition that he respected the marital privileges of the senior; hence he would have to seek his mate from without the band; and the conditions in which he lived with the female members of his own family gave origin to the curious etiquette of "avoidances" which is still to be found amongst some savage races and the history of which has been such a puzzle to anthropologists. The later chapters of Mr. Atkinson's essay are mainly devoted to this subject, and certainly if his hypothesis be accepted it may serve to unravel some tangled problems. The work is one which will undoubtedly greatly stimulate anthropological research and the central idea which it contains will be tested in the light of new researches. The author wrote from a place far away from books; his theory was the outcome of patient and prolonged work and the essay is vigorous and virile. It may indeed prove caviare to the general reader and even repugnant to those who, like the late Lord Beaconsfield, are "on the side of the angels"; nor will it commend itself to those who are not interested in, or are entirely ignorant of, the manners and habits of savage races. A preliminary acquaintance with Westermarck's history of marriage[1] and Spencer and Gillen's book on the Australian natives[2] will add to the interest of Mr. Atkinson's essay, and that Crawley's "Mystic Rose"[3] and the parts of Frazer' "Golden Bough"[4] which deal with marriage rites and customs include details instructive in this connexion. Mr. Lang tells us in his preface that he is indebted in various ways for assistance to, amongst other people, Mr. Crawley, who *not only* "*read the book, or most of it,*" but also "collaborated most efficiently in the way of suggesting objections."

The Diagnosis and Modern Treatment of Pulmonary Consumption, with special reference to the Early Recognition and the Permanent Arrest of the Disease. By ARTHUR C. LATHAM, M.A., M.D. Oxon., M.A. Cantab., Assistant Physician and Lecturer in Practical Medicine at St. George's Hospital, Assistant Physician at the Brompton Hospital for Consumption and Diseases of the Chest. London: Baillière, Tindall, and Cox. 1903. Pp. 215. Price 5*s*.

THIS volume contains a series of articles which have appeared in the medical press during the last few years. Dr. Latham has published them in a collected form in the hope that they may prove of service as a practical guide to the diagnosis and treatment of pulmonary tuberculosis.

---

[1] The History of Human Marriage. By Edward Westermarck, Lecturer on Sociology at the University of Finland, Helsingfors. London: Macmillan. 1891.

[2] The Native Tribes of Central Australia. By Baldwin Spencer, M.A., and F. J. Gillen, Special Magistrate and Sub-protector of the Aborigines, Alice Springs, South Australia. London: Macmillan. 1899.

[3] The Mystic Rose: A Study of Primitive Marriage. By Ernest Crawley, M.A. London: Macmillan. 1902.

[4] The Golden Bough: A Study in Magic and Religion. By J. G. Frazer, D.C.L., LL.D., Litt. D. Second edition. London: Macmillan. 1900.

The first three chapters are concerned with the diagnosis of the various forms of pulmonary tuberculosis, acute and chronic. The pages devoted to this subject will well repay perusal. Since the discovery of the tubercle bacillus the task of making a positive diagnosis of tuberculous disease of the lungs has been rendered far more easy, but many cases still present themselves with a history strongly suggestive of tuberculosis in which expectoration is either absent or bacteriological examination yields a negative result. Dr. Latham enters very fully into a description of the physical signs and symptoms which help the physician in arriving at a diagnosis. His remarks on the use of tuberculin for diagnostic purposes are interesting. When the disease is so slight that a diagnosis cannot be made by means of the physical signs, and no tubercle bacilli can be detected in the sputum, he believes that one, two, or three small injections of Koch's old tuberculin may be employed without the slightest risk. He places great reliance on this test although he adduces evidence to show that in certain cases a reaction may be obtained when tuberculosis is absent, but such instances must be very rare, as Professor Koch has stated that after an experience of some 3000 cases he considers the tuberculin test to be almost absolute.

Two chapters are devoted to the method of treatment as carried out in a sanatorium. Dr. Latham's views on this subject were set forth at length in the essay which obtained the first prize in the competition on the erection of the King's Sanatorium and which was published in THE LANCET of Jan. 3rd of this year. An interesting summary of other forms of treatment will be found in Chapter VII. The use of creasote, formic aldehyde, tuberculin, and other drugs is criticised, but Dr. Latham evidently does not consider them to be of great value, especially when compared with the sanatorium treatment. The chapter on the Treatment of Special Symptoms contains numerous valuable hints as to the treatment of cough, pain, night sweats, hæmoptysis, and other symptoms which so frequently arise in patients suffering from pulmonary tuberculosis. The prescriptions he suggests will be found useful and trustworthy.

The last chapter in the book is headed "Special Considerations" and contains many remarks on matters connected with tuberculosis, a few of which are contrary to the views held by some of the leading authorities. Dr. Latham, however, has the courage of his convictions and has acted quite rightly in thus plainly stating his opinions. For instance, he insists that as far as possible all patients should be treated under the same climatic conditions as those which they are likely to experience in their subsequent life. We consider this to be perfectly sound advice. It is true that patients with very limited disease do well at high altitudes and on returning to ordinary conditions suffer no harm, but such patients make equally good progress in the sanatoriums in this country. Dr. Latham likewise throws doubts on the hereditary nature of the disease. He quotes the statistics of Dr. J. Edward Squire which show that the difference in the incidence of the disease in the offspring of tuberculous and non-tuberculous parents is very small. Dr. Latham remarks that these figures are remarkable, as the children of tuberculous parents who are the victims of active disease must in most cases, unless the necessary precautions are taken, be more exposed to the risk of infection. The statistics would appear to suggest, he says, that the children of tuberculous parents possess some natural immunity to the disease, for otherwise the percentage of children who develop tuberculosis should be much greater when the parents suffer from the disease than when they do not. As far as we are aware this is a perfectly original suggestion. It is one, however, that is worthy of careful consideration, although it is apparently contrary to views hitherto commonly held.

A System of Physiologic Therapeutics. Edited by SOLOMON SOLIS COHEN, A.M., M.D., Senior Assistant Professor of Clinical Medicine in Jefferson Medical College, Philadelphia; Physician to the Jefferson Medical College Hospital. Vol. V., Prophylaxis; Personal Hygiene; Civic Hygiene; Care of the Sick. Illustrated. London: Rebman, Limited. 1903. Pp. 539. Price 12*s.* 6*d.*

THIS volume contains an epitome of what is essentially the natural history of medicine, including excellent contributions on matters concerning the origin, dissemination, and prevention of disease. The editor has taken a very wide view of etiology; he rightly thinks that in a consideration of the cause of disease the psychic as well as the physical characteristics of men must be taken into account, that due attention must be paid to heredity as well as to the constitution of the individual, and likewise that notice must be taken of the intrinsic failures and perversions as well as environmental factors that may disturb mind and body. He further maintains that the artificial conditions of civilisation, the diversity, complexity, and strenuosity of the activities of modern life, and the reciprocal influences of individuals upon communities and of communities upon individuals render it necessary, alike in the study of personal hygiene and of public health, to consider, at least by allusion, many aspects of sociology. The purview so indicated involves questions of economics, of engineering, of manufactures, of architecture, of pedagogics, of commercial intercourse, of taxation, and of municipal government. It will be thus seen that Dr. Cohen has set himself a large task if his ideas are to be carried out in full. A perusal of this book will show that the material collected together is most interesting and varied and that he may be congratulated, as far as the fifth volume is concerned, on the success of his endeavours.

The work is divided into three parts. Part I. is headed "The Origin and Prevention of Disease" and is written by Dr. J. McFarland, professor of pathology and bacteriology in the Medico-Chirurgical College, Philadelphia, and Dr. W. Wayne Babcock, lecturer on pathology and bacteriology in the Medico-Chirurgical College. A vast number of topics are discussed in connexion with the etiology and prophylaxis of disease and its diffusion. Especially interesting are the remarks on the methods of transmission of disease by animals and the modes of parasitic invasion, action, and elimination. The prophylaxis of the infectious fevers naturally holds a prominent place, and the introduction of summaries in tabular form makes the more important points easily accessible for reference.

Part II. is devoted to Civic Hygiene and is written by Dr. H. Leffmann, professor of chemistry and toxicology in the Women's Medical College of Pennsylvania. In this section chapters will be found on Municipal Health Organisation, Food- and Water-supply, and Disposal of Waste.

Part III. is entitled "Domestic and Personal Hygiene; Nursing and Care of the Sick-room." The author is Dr. Albert Abrams, consulting physician to the Mount Zion Hospital and to the French Hospital, San Francisco. Dr. Abrams enters fully into a consideration of the hygiene of dwellings, of the school, and of travel. A chapter is devoted to Personal Hygiene, another to Hygiene of Special Periods, and a third to Hygiene of the Diatheses. A carefully prepared index adds to the value of the publication as a work of reference.

LIBRARY TABLE.

Practical Pharmacy and Prescribing. By JAMES CALVERT, B.Sc., M.D. Lond. London: H. K. Lewis. 1903. Pp. 110 and interleaved. Price 4*s.* 6*d.*—This is a second edition of an excellent little notebook which is in use by the students of medicine at St. Bartholomew's Hospital. It is divided into two parts, the first part dealing with practical pharmacy and the second part with prescribing. The first part, as Dr. Calvert acknowledges, was written upon a basis given to him by Sir T. Lauder Brunton, to whom he acted as demonstrator in pharmacology at St. Bartholomew's Hospital. In the second part, dealing with prescriptions and incompatibles, we have the author's attempt to interest the students just before they enter upon their practical work in the wards, and while their chemistry is still fresh in their minds, in the importance of practical therapeutics so that "when they pass into practice they may not be absolutely chained to the formulæ of the hospital pharmacopœia or of the manufacturing chemist." The book is interleaved throughout that the writer may record his own experiences and make memoranda of successful preparations.

A Model Sanatorium for Tuberculosis. By ALEXANDER G. R. FOULERTON, F.R.C.S. Eng., D.P.H. Cantab., and R. LANGTON COLE, F.R.I.B.A. London: Rebman, Limited. 1903. Pp. 31.—This small book, being an essay submitted in the recent competition for the King's Sanatorium Prize, sets out in very clear language, with ground plans, sections of elevations and measurements, a model sanatorium for the treatment of pulmonary tuberculosis. The authors adopt the pavilion system as one combining as far as possible the separate cottage system with facilities for careful supervision. Where it can be managed the aggregation of patients under cover indoors is avoided, although a large winter garden provides opportunity for a certain amount of recreation in common. The estimated cost of erecting the sanatorium is £115,000 and many features of the building are common to the prize plans which we have already published in our columns.

A Manual of Toxicology. By ALBERT H. BRUNDAGE, A.M., M.D., Phar. D., Professor of Toxicology, Physiology, and Hygiene in the Brooklyn College of Pharmacy. Second edition. New York: The Henry Harrison Company. London: Baillière, Tindall, and Cox. 1902. Pp. 375. Price 6*s.*—This volume is intended to be "a concise presentation of the principal facts relating to poisons, with detailed directions for the treatment of poisoning." The author has succeeded in producing a work which will serve as a ready means of review of the salient points of toxicology and as a convenient book for reference in cases of emergency. The first part deals with general considerations, such as the classification of poisons and the methods of procedure to be adopted when symptoms and circumstances indicate that a poison has been taken. In the second part the poisons are considered seriatim, the various drugs being taken in alphabetical order, for convenience of reference a good plan. The fatal dose is first given and it is understood that the doses are for adults and, of course, are subject to modification according to the circumstances of the case, such as whether the drug has been taken on a full or an empty stomach. The symptoms are then described, the more important being printed in bold-faced type; the same plan of alteration of type is also adopted in the paragraphs on treatment, so that the main points can be seen at a glance. Each poison is described briefly though at sufficient length for all purposes desired by the practitioner to whom the work would really be useful in an emergency. The book is not one which we should recommend to students for examination purposes, for too much is included. The author has spared no pains in rendering his book as complete as possible and has included not only the substances which are usually recognised as poisonous but also those which only occasionally produce alarming symptoms. The tests for poisons are duly given and also the outline of procedure in searching for poisons is accurately indicated. The post-mortem appearances are placed towards the end of the book. We think a more convenient place would have been in the second part of the book, where the symptoms and treatment in connexion with the respective poisons are described.

Medicine for the Mind. London: St. Martin's Press. Pp. 138. Price 2*s.* net.—This is a funny little book of quotations in which the author attempts to tabulate the defects of the mind and to supply a quotation from a well-known author in remedy of each defect. A book with such a scheme is foredoomed to failure. As a collection of quotations it has some merit, but not as an adjuvant in mental therapeutics.

Hindustani Grammar Self-Taught. By Captain C. A. THIMM. London: Marlborough and Co. 1902. Pp. 118. Price 2*s.*—This book is a sequel to the author's "Hindustani Self-Taught" which was published a few years ago and contains the essential points and rules of grammar with notes to illustrate the construction of the language that will be needed by those who may require to pass Government examinations. We observe that the dictionary of Hindustani every-day words which is appended to the grammar contains no words of medical significance but the colloquial vocabulary is profuse. Urdu is the language most widely spoken in India and a mere smattering of it is of service to all whose business takes them to our Eastern empire. Many of our countrymen who pass long periods of their lives, whether in political, military, or civilian employ, in our Indian empire do contrive to acquire a rudimentary acquaintance with Hindustani and to such Captain Thimm's book will be of practical use.

The Rearing of Infants. By ROBERT GUY KELLETT, L.R.C.P., L.R.C.S. Irel. London: A. H. Jones. 1903. Pp. 40. Price 6*d.* net.—This little pamphlet is addressed to the public and is justified by the sacrifice of infant life which is revealed by the annual reports of the Registrar-General. "There are few girls," says the author, "...... and still fewer women who do not think that by virtue of some instinct of their sex, and without any special thought or training they are quite capable of bringing up an infant." This is a melancholy truth and any book that can impress upon the public that it is the duty of a young wife about to become a mother to learn something of the responsibilities so soon to be thrust upon her is fulfilling a good object. Mr. Kellett's little work is quite elementary, remarkably simple in language, and, as far as it goes, it is sound. It is not likely to prevent cases of serious illness from obtaining medical notice.

The Law of Mental Medicine. By THOMAS J. HUDSON, Ph.D., LL.D. London: G. P. Putnam's Sons. Chicago: A. C. McClurg and Co. 1903. Pp. 281. Price 7*s.* 6*d.*—This book is a correlation of the facts of psychology and histology in their relation to mental therapeutics and aims at placing mental therapeutics on a firm scientific basis. The object of the book is therefore excellent, but when we look closely into it we find it full of suppositions upon the physical mechanism through which mental health is affected; animal magnetism (whatever that may signify), hypnotism, and thought-transference are treated as though more was proven concerning them than any scientific thinker can allow, and generally the book, although suggestive, leaves the impression of being speculative and unsound.

The Ventilation, Heating, and Management of Churches and Public Buildings. By J. W. THOMAS, F.I.C., F.C.S. London, New York, and Bombay: Longmans, Green, and Co. 1903. Pp. 140. Price 2*s.* 6*d.*—In this little book a great deal of information is compressed into a very small compass, for within its modest number of pages we find discussed fairly thoroughly the physical laws bearing upon th ventilation of buildings. The book is well illustrated, the illustrations showing the result of many experiments on wind action and intermittent air currents. Ventilation is, of course, a subject on which much remains to be said, for upon many of the most important points comprised under the word differences of opinion exist among scientific men; but Mr. Thomas deals with the matter in a practical manner and his book should prove of value to all who are in any way concerned with the question of house construction. The chapters on How Ventilation can be Improved and the Ventilation of New Buildings will in particular repay perusal. The last chapter contains instructions for the caretaker, but we think it is asking too much of the average porter to expect him to take intelligent notice of prevailing winds and temperature.

JOURNALS AND REVIEWS.

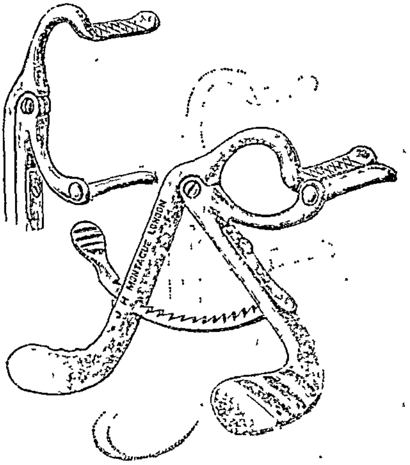
Journal of the Royal Army Medical Corps. No. 2, August, 1903. London: John Bale, Sons, and Danielsson, Limited. Price 2s. net.—The second number of this new medical journal fulfils the expectations realised by the first issue and Major R. H. Firth, R.A.M.C., is to be congratulated upon the success under his editorship. The first article, "Notes on Surgical Experiences of the Boer War," by Surgeon-General W. F. Stevenson, C.B., R.A.M.C., discusses the "humane" and "merciful" effects of the small-bore rifle bullet, the conclusion of the author being that a little can be said in favour of the "humanity" of the modern bullet, but only a very little. Lieutenant F. Bruce, R.A.M.C., contributes a paper entitled "Experiences of X-Ray Work during the Siege of Ladysmith." There are notes on a case of Spear-wound of the Heart, with Recovery, by the late Captain T. McArdle, R.A.M.C., and on two cases of Perforating Gunshot Wound of the Skull, by Lieutenant-Colonel S. F. Lougheed, C.M.G., R.A.M.C. The illustrations to these papers are excellently reproduced. A very interesting article is a Historical Retrospect of the Army Surgeon in Britain prior to the Sixteenth Century, in which the author, Captain H. A. L. Howell, R.A.M.C., acknowledges indebtedness to the late Sir James Simpson for the archæological researches relating to the surgeon in the Roman armies in Britain.

The Practitioner.—The issue of this magazine for August contains a paper, "The Treatment of Gout in Carlsbad," a comprehensive contribution from Dr. B. London, which includes a fairly full discussion of the much vexed etiological and pathological questions surrounding the subject of *arthritisme.* Dr. Leonard Williams contributes an article upon Peripheral Neuritis of the Alcoholic Type, containing the accounts of two cases which are interesting and important mainly from the apparent certainty with which special etiological factors could be excluded. Dr. Williams regards no explanation of the facts of peripheral neuritis as satisfactory which fails to include not only both alcohol and arsenic but also "some other factor or factors of which only this can be said, that they bear no ascertainable relationship either to the one or to the other." Mr. Thomas B. Futcher supplies some careful observations on points of metabolism in gout with special reference to the relationship between the uric acid and the phosphoric acid eliminations. These are based on observations made for Dr. Osler. Dr. S. Vere Pearson and Mr. J. P. L. Mummery, in a very practical paper upon the After-treatment of Empyema in Infants, lay stress on the importance of early removal of the drainage-tube and on the evil of washing out the cavity with antiseptics. Importance is also attached to careful observation of the physical signs upon the side of the disease after the operation and especially to attention to general symptoms and careful treatment of the child's general condition.

New Inventions.

A NEW GAG.

THE instrument shown in the illustration possesses some qualities which render it peculiarly suitable for certain anæsthetic emergencies. Operations on the ear and brain necessitate a fixed position of the head which precludes the
easy introduction of either dis-
turbing the operator f the head
itself. This is clearly s With the
gag now described the handle lies in the same vertical plane as the blades when the latter are open and in position against the upper and lower jaws. The blades when closed



are practically on the same horizontal level, and are, therefore, easily inserted between the teeth. There are two ways of using the gag—namely (1) with the handle downwards as shown in the illustration; and (2) with the handle upwards on the cheek, best seen in the figure by turning it upside down. The latter position will be found the more convenient of the two for opening the mouth during the progress of an operation as no lateral movement of the head or face need be caused. The anæsthetist standing or sitting in front of the patient can easily place the instrument in position and swab out the throat or seize the tongue, as the case may be, without the least trouble or disturbance. I have used this gag for keeping the mouth open and fixed in many nose and throat operations, and I can strongly recommend it for rapidity of introduction and strength of grip as well as for simplicity of action and general utility in this class of cases. Originally devised for use during mastoid operations, I have found the gag extremely serviceable in adenoid and tonsil cases. The linear arrangement of the closed blades renders introduction easy, and there is a large space available to the operator when the jaws are fixed, owing to the wide outward sweep of the arms. I am indebted to Mr. J. H. Montague, 101, New Bond-street, London, W., s.

Weymouth-street, W.

MEDICINE AND THE LAW.

Medical Men and Death Certification.

A SINGULAR charge of petty fraud at the recent Glamorgan assizes drew from the grand jury and from Mr. Justice Channell, before whom the prisoner pleaded guilty, certain strictures upon the conduct of Mr. H. E. Charles, a medical man practising at Swansea, which the medical profession will regard as unjust and undeserved. In April last

Mr Charles had brought to him a child suffering from measles and chest complications. On the following day the mother came again and informed him that the child was dead and as this in no way surprised him at the mother's request he gave her the usual certificate, assigning as the cause of death the conditions which he had observed. Medical men who have had experience of general practice will see nothing lax or improper in Mr. Charles's conduct, nor will they find anything in the law ordering any different course to be taken. As a matter of fact, however, the child was alive and the mother had represented it to be dead and had obtained the certificate in order to defraud an insurance company of £3 10*s.* This sum she was charged with obtaining by false pretences and it was the fact that Mr. Charles had given a certificate without seeing the dead body which gave occasion for the observations of the judge and for a presentment by the grand jury, the members of which no doubt took their cue from observations made by his lordship in charging them. Mr. Justice Channell, it is true, called Mr. Charles into the witness-box and to some extent permitted him to explain; but he did not apparently accept his explanation or appreciate the fact that what had occurred was due to the provisions of the law and to the practice which has arisen under it. The law relating to death registration and burial is far from perfect and in the public interest alterations might be made in it. If, however, such alterations were to involve the inspection of every dead body by a medical man before the fact of death was established such inspection would have to be made a matter of legal obligation for which the relatives would be compelled to afford facilities and for making which the medical man would have to be remunerated at the public expense. At present a medical practitioner insisting upon seeing the body after being told by a relative whom he has no reason to disbelieve that his patient is dead in many instances would incur odium and would give unnecessary pain. The question of payment and of waste of time also would arise, particularly in such cases as that under discussion. Little or nothing, however, would be achieved towards protecting the public, because in the absence of any compulsorily uniform practice persons meditating fraud would select a medical adviser who would rely upon the information given by them. In the case in question Mr. Charles might have used in his certificate the phrase "as I am informed," and no doubt medical men, to whose notice his unpleasant experience is brought, will in future be careful to do this where the body has not been seen by them after death. On the other hand Mr. Charles might, by insisting upon seeing the body, have prevented a fraud upon an insurance company, but the protection of possibly interested commercial bodies, well capable of protecting themselves, forms no part of the medical man's already burdensome public duties. A certain want of lucidity in the dicta of Mr. Justice Channell, as reported in the local press, makes it difficult to say the precise extent of the precautions which he would impose upon the medical profession. The mere inspection of the dead body would establish the fact of death and so prevent a fraud such as that exposed at the Glamorgan assizes, but it could not insure the detection and punishment of cunningly carried out crime of another class. The following observations, however, are ascribed to the learned judge: "Oh, dear me, you have nothing to do but hold your hand and give it to the coroner." "If you have seen the child once and are told that it was subsequently dead I don't think you are justified in certifying it died from the disease of which you happen to know it is suffering. A little more caution is necessary." It is not clear from this whether Mr. Justice Channell thought that Mr. Charles might have left the case in question to the coroner for investigation or that the mere sight of the dead body would have put him in the right. Any such examination of the body as would with any certainty detect crime, should any crime accelerating death have been committed, would be entirely beyond the power of the medical man upon such an occasion, and again it must be pointed out that the medical practitioner is not, and should not be, a detective. In our view, if the law is in any respect unsatisfactory it is within the scope of the duties of judge or grand jury to aid in bringing about amendment by calling attention to defects. To censure an honourable man who has not infringed the law because in a particular instance the law has not proved effective to prevent a petty crime being perpetrated by an unscrupulous person is not likely to increase the respect with which the administration of justice should be regarded.

THE
BRITISH MEDICAL ASSOCIATION
MEETING AT SWANSEA.

◆

THE SECTIONS.
SURGERY.
FRIDAY, JULY 31ST.

Mr. **SINCLAIR WHITE** (Sheffield) read a paper on

Two Cases of Ascites secondary to Alcoholic Hepatitis treated successfully by Operation.

In the first case a woman, aged 38 years, who had been alcoholic for four years, had much ascites. She had been tapped twice and her liver was hard and nodular. The abdomen was opened and the omentum was found forming a hard irregular mass. The upper surface of the liver was rubbed with gauze and the anterior border was stitched to the diaphragm and the anterior abdominal wall was stitched to the great omentum. A drainage-tube was inserted just above the pubes. The operation caused a great deal of shock but the patient soon rallied and was now quite well. In the second case a woman, aged 34 years, had been in the habit of taking much alcohol. She had been tapped three times. The same operation was performed. The drainage-tube was kept in for four weeks and the patient did not begin to improve for two months, but she was now well. As a result of this operation new venous channels formed in the adhesions and conveyed the portal blood into the systemic veins. Mr. White thought that the nutrition of the hepatic cells was also improved. Up to the present more than 100 cases of this operation had been recorded.

Mr. **H. BETHAM ROBINSON** (London) read a paper on

Separation of the Acetabular Epiphysis of the Femur.

He thought it probable that many cases were mistaken for hip disease. The centre in the head appeared at the age of one year and the epiphysis united with the neck in the twentieth year, so that between those ages separation of the epiphysis might occur. In one case a lad, aged 19 years, fell on to his left hip and he limped for three months and when examined the tip of the great trochanter was found to be half an inch above Nélaton's line. The joint was opened and the separated epiphysis was removed. After the operation the joint was kept at rest and later massage was employed, but no weight was allowed to bear on the limb until six months after the operation. In another case a lad, aged 17 years, fell and at first there seemed to be no change as regards Nélaton's line, but later the tip of the great trochanter was half an inch above Nelaton's line. There was only a slight range of movement. When the joint was opened the epiphysis was found to be separated and rotated forwards. In a typical case the limb was everted but there was not the rigidity of hip-joint disease. The gluteal fold was present but raised. The condition was probably not rare but very few cases had been published. Mr. Robinson was inclined to suggest that the primary change was similar to that giving rise to the coxa vara of adolescents. Probably many cases were looked upon as hip disease. The best treatment was to remove the separated epiphysis.

Mr. **WILLIAM SHEEN** (Cardiff) read a paper on

A Case of Operative Treatment for Cirrhosis of the Liver.

The patient was a sergeant-instructor in the army; he had had symptoms of portal obstruction for about a year and had been tapped four times. The abdomen was opened and the great omentum was found to be adherent to the peritoneum of the anterior abdominal wall. The convex surfaces of the liver and spleen were rubbed with gauze and a drainage-tube was inserted above the pubes. The abdomen was firmly strapped with broad bands. The man had fully recovered and had had no return of the ascites. Mr. Sheen considered that the continuous drainage and the firm strapping were the essentials of the operation.

Mr. **R. W. MURRAY** (Liverpool) read a paper on

The Ultimate Results in a Series of 88 Cases of Fracture of the Tibia and Fibula.

The paper was accompanied by a table of all the cases with details of each case. He remarked that most surgeons seemed to be satisfied with the results, but his personal examination of a series of cases made him think that the results were not good. He found that the direction of the fracture had much influence on the time during which the patient could not work. If the fracture were transverse on an average three and a half to four months elapsed before the utility of the limb was completely restored, but if the fracture were oblique on an average seven months elapsed before the patient could do his ordinary work. One cause of this long duration of uselessness of the limb was, in Mr. Murray's opinion, the uncomfortableness of an ordinary back splint. When the fracture was oblique the limb rotated outwards even though the foot was fixed. He showed a form of splint which was the most useful. The foot was held at an angle greater than a right angle and the foot was inclined outwards. This was the true natural position of rest. The chief obstacles to "setting" a fracture were hæmorrhage into, and inflammation of, the soft parts and piercing of fasciæ by the sharp ends of the bone. In many cases operative treatment was desirable, especially if the fracture was in the lower third of the limb and if a skiagram showed that less than two-thirds of the fractured surfaces were in contact. In Pott's fracture the prognosis was not so good as when both bones were broken. In seven out of 31 cases utility of the limb was not fully restored.

Mr. Betham Robinson mentioned that plaster-of-Paris, as used at St. Thomas's Hospital, completely prevented displacement.

Mr. Reginald Harrison (London) had found that division of the tendo Achillis was very useful in obtaining correct apposition of the fragments.

Mr. O. P. Childe (Southsea) considered that in all fractures of the leg the knees should be fixed.

Mr. A. H. Tubby (London) was of opinion that if by the fourth day all ordinary means had failed to obtain a good position of the fragments it was best to cut down on the fractured ends and to fix the bones together by some mechanical means.

Mr. R. H. Anglin Whitelocke (Oxford) was inclined to think that the interposition of muscle or fascia was a common cause of difficulty in obtaining correct apposition.

Dr. Alfred Sheen (Cardiff) had used plaster-of-Paris bandages extensively and was very satisfied with them. One great advantage was that the patient, if there was no swelling, need not be detained in the hospital for more than a day or two.

Mr. Jordan Lloyd (Birmingham) said that surgeons were apt to neglect such simple injuries as fractures and to leave them to the house surgeons. He thought that fractures were treated now worse than they ever were treated.

Mr. Murray, in reply, said that at the present time a capable surgeon need not fear making a simple fracture compound and therefore operation in suitable cases was clearly indicated.

Mr. P. J. Freyer (London) read a paper on

A Further Series of 32 Cases of Total Extirpation of the Prostate for Radical Cure of Enlargement of that Organ.

A year ago at the Manchester meeting of the British Medical Association Mr. Freyer gave details of his first series of 21 cases of total extirpation of the prostate. He now brought forward a further series of 32 cases of the operation performed by him during the year that had elapsed since then and showed a large number of prostates which had been removed. The first 24 of this second series had already been described in various lectures and papers and so he confined his account to the remaining eight cases. In one case, that of a man aged 81 years, prostatic symptoms had lasted ten years and three years ago vasectomy had been performed by another surgeon without benefit. The prostate was removed entire suprapubically; the patient began to pass urine naturally one month later and was now in excellent health. In another case, that of a patient aged 62 years, a "middle lobe" as large as a Tangerine orange had been removed by another surgeon but a permanent suprapubic fistula remained. Mr. Freyer removed the prostate suprapubically and the patient made a good recovery and could pass and retain his urine naturally. In a third case, that of a patient aged 74 years, there had been retention on several occasions. The operation was a very rapid one, only two minutes elapsing from the commencement of the suprapubic incision to the complete removal of the prostate. Mr. Freyer had performed the operation in 53 cases, the ages varying from 57 to 81 years. All the patients were in broken health and many had severe complications such as cystitis, pyelitis, and diabetes. Excluding two cases still under treatment there remained 51 cases and of these 46 were successful both immediately and remotely, the patients being able to retain and to pass their urine naturally. One died suddenly from heat-stroke on the tenth day, two died from acute mania after the wounds had practically healed, one died from coma due to retention of morbid products in his urine which had set in before the operation, and one died from pneumonia seven days after the operation. Even counting all these five deaths which occurred in connexion with, though they were not due to, the operation the mortality was only 10 per cent. Among the last 19 completed cases no mishap of any kind had occurred. In no case did a permanent fistula remain and in no case was there septicæmia, the temperature throughout remaining normal. Mr. Freyer suggested that patients who did not die from septicæmia on first entering on catheter life gradually became more or less immune from slow absorption of toxins over lengthy periods.

Mr. Reginald Harrison referred to two cases which he had operated on during the last two weeks. In one patient, aged 74 years, a suprapubic cystotomy was done and a stone was found impacted between the two prostatic lobes and complete obstruction was present. The prostate was removed and the patient was doing well. In the other patient, aged 60 years, by a lateral incision in the perineum he was able to enucleate an encapsuled tumour in the prostate. He considered the perineal route a very good way of approaching an enlarged prostate.

A medical man who was present and on whom Mr. Freyer had operated spoke of his personal experiences. He had had great difficulty of micturition for about four years and vasectomy had been performed without benefit. Then Mr. Freyer had removed the prostate by the suprapubic operation and since then he had had full control over the bladder.

Mr. A. B. Mitchell (Belfast) described a case of enlarged prostate in which he had performed prostatectomy. He did not consider the perineal so easy as the suprapubic operations.

Dr. H. T. Herring (London) pointed out that many of the symptoms which were often attributed to enlargement of the prostate were really due to the concomitant sepsis. The continuance of these symptoms was brought about, not by one inoculation, but by the constant and repeated introduction of septic matter. If care was taken to prevent septic infection of the bladder the passage of a catheter two or three times a day would keep the patient in good health. Such a case would not be suitable for operation. The prevention of sepsis could be effected by drilling the patient from the beginning in details of asepsis. He considered that this operation should be reserved for exceptional cases when all other methods had failed to give relief.

Mr. Jordan Lloyd said that Mr. Freyer's operation was entirely new and not identical with preceding operations. He had found it difficult to remove prostates which were causing obstruction and yet were not much enlarged.

Mr. Betham Robinson mentioned that Mr. Freyer in his account of one of his cases had said that he removed a piece of the recto-vesical fascia. This would open up all the connective tissue of the pelvis and lead to extensive cellulitis.

Mr. Freyer, in reply, said that he had removed only a thin layer and not the whole thickness of the recto-vesical fascia. Theoretically it was possible to keep a bladder aseptic in spite of regular catheterism, but practically it was almost impossible.

Mr. Tubby read a paper on

A Method of treating by Operation Paralysis of the Upper Root of the Brachial Plexus (Erb-Duchenne Type).

In this condition, due to injury of the root of the fifth cervical nerve, there was loss of power at the shoulder and at the elbow. He treated these paralyses by muscle grafting. He restored the power of flexion to the elbow by splitting off a portion of the outer head of the triceps and attaching it to the biceps. The loss of power at the shoulder was treated either by *splitting off a portion of the pectoralis* major, taking it over the acromion, and inserting it into the deltoid, or by joining a portion of the trapezius to the deltoid. The latter was the better method.

[illegible] that he, in conjunc- [illegible] per in the Section of [illegible] orm of paralysis and its treatment were discussed. It was necessary to test the cervical nerve *roots* by weak faradic currents, so as to know which were the paralysed fibres. Sometimes only half of the fifth cervical root was paralysed. The treatment they had adopted was to suture the fifth cervical nerve to the sixth with very good results.

insanity, though obvious, was of recent origin and had not become permanently established or confirmed. Dr. Yellowlees then referred to the general rules to be followed in the treatment of incipient insanity—viz., removal of the patient from the surroundings where he usually lived, experienced nursing and skilled medical treatment, pleasant companionship, good food, rest, and suitable amusement. Though general principles were thus stated, their value, he said, lay in their judicious application. He hoped that the reception "houses" for incipient cases of lunacy which the London County Council was about to provide would be under the jurisdiction of the Commissioners in Lunacy and placed in the charge of skilled resident physicians who had had experience in the diagnosis, care, and treatment of lunacy in its various forms. He thought that all asylums for acute and curable cases of insanity should be small.

A discussion followed the reading of this paper in which Dr. R. S. STEWART (Glamorgan), Dr. BOYLE, and Dr. FLASHMAN took part, after which the PRESIDENT spoke on the importance of the scheme of treatment of incipient insanity and Dr. YELLOWLEES briefly replied.

Dr. STEWART read short portions of a paper on Wages, Lunacy, and Crime in South Wales, and Dr. A. T. SCHOFIELD read a few abstracts of a paper on Psycho-Therapeutics, its Use and Abuse. Both these papers were read without discussion owing to lack of time and the remaining papers on the programme were taken as read.

LARYNGOLOGY AND OTOLOGY.

THURSDAY, JULY 30TH.

Dr. P. MCBRIDE (Edinburgh) and Professor ARTHUR HARTMANN (Berlin) introduced a discussion on

The [illegible] on the Temporal Bone in
[illegible] le-Ear Disease.

Dr. MCBRIDE in his opening address gave an interesting account of the history and development of operations upon the temporal bone from 1649, when Riolanus suggested the first operation of opening into the mastoid cells. It is said to have been proposed as a remedy in cases of occlusion of the Eustachian tube. The subsequent development of the technique of the mastoid operation was traced down to the present time.

Professor HARTMANN confined himself to some practical points and to showing some anatomical preparations in illustration of them. Speaking of acute inflammation he said that in opening the mastoid the antrum, as a rule, should be opened so as to allow free communication with the tympanic cavity. Only in those cases of abscess of the mastoid in which the internal wall of the abscess during operation appeared to be healthy and in which there was no swelling of the posterior and superior wall of the meatus and of the upper part of the membrane should they confine themselves to the removal of diseased bone and not open the antrum. If there were any symptoms or signs pointing to an extension of suppuration to the middle or posterior cranial fossa, then the bony parts should be removed until the dura mater was exposed. In order to effect a rapid and lasting cure by this operation the entrance to the cavity of the mastoid must be made very wide. All the bone over the diseased parts, chiefly the posterior and inferior edges of the bony cavity, must be removed and also the external part of the posterior wall of the meatus; by so doing the soft integuments afterwards lined the cavity. Speaking of the treatment of chronic suppuration of the middle ear, he said that the principle of the radical operation was that all the affected parts of the tympanic cavity and mastoid were rendered perfectly accessible and visible. For this purpose (1) all bone external to the affected parts must be removed; and (2) the external meatus must be considerably enlarged. Professor Hartmann here demonstrated several preparations showing the relationship of the facial nerve to the inner and posterior wall of the meatus. In the treatment of labyrinthine suppuration he said that the vestibulum could be opened without difficulty by removing the stapes from its window. If it were not to be seen the vestibulum could be opened by the burr, but they must avoid going upwards in order not to injure the facial nerve; by going too deeply the carotid might be injured. In the majority of cases purulent inflammation of the labyrinth extended from the mastoid through the semicircular canals. The operation could be performed from the semicircular canals or from the promontory according to the seat of the disease. Preparations were demonstrated in illustration of these points. Before operating for chronic suppuration he recommended that the tympanic cavity and the antrum should be cleansed as thoroughly as possible by means of a suitable cannula such as he had devised; he had seen many cases in which the radical operation had been advised but after cleansing the parts in the way mentioned the discharge ceased and by a few repetitions of this purification the necessity for an operation was obviated. He had met with similar experience in the treatment of suppuration of the antrum of Highmore. He said that, as a rule, after the operation several spots were left covered with epithelium, such as the inferior and superior wall of the meatus, also a small piece of the internal part of the posterior wall, some parts of the surface of the internal and upper wall of the tympanic cavity and the antrum; from these spots epidermisation could extend. By enlarging the opening of the meatus and removing the edges in a manner recommended for acute abscess, the soft parts extended inwards and only as mall cavity was left to be covered. The best grafts were the natural extensions from the soft parts in the cavity. The enlargement of the external meatus might be effected by means of Korner's flap or by the Y-shaped cut of Siebenmann. The more they enlarged the meatus the more they diminished the external surface of the wound cavity and epidermisation of the internal surface could more easily and readily take place by extension from the edges of the enlarged meatus. Epidermisation by implanting skin grafts was not now performed in Germany so much as formerly. Dr. Hartmann said that by proceeding in the manner he had recommended, by leaving some parts of the internal surface covered with epithelium, by removing the edges so that the whole cavity was rendered very small, and by enlarging the external meatus considerably, they seldom had to resort to skin-grafting and the wound behind the concha could be sutured after the operation.

Dr. J. DUNDAS GRANT (London) considered that Dr. Hartmann had taken a very practical course in dividing the operation into two groups according as they were practised for acute or chronic inflammation. The two operations were entirely different. It had been said that the radical operation was performed too often; in his opinion the non-radical operation for acute inflammation was performed too seldom. He preferred to work with a firm bent probe, such a one as devised by himself, or Stacke's guard, but it in itself was capable of doing damage unless it was held by an experienced assistant; the guard itself might be the agent in damaging the facial nerve.

Dr. R. C. ELSWORTH (Swansea) showed some preparations of the temporal bone cut to demonstrate an accessory antrum above and behind the antrum itself, and also a small vein connected with this accessory cavity.

Professor GLUCK (Berlin) demonstrated by means of diagrams the operation which he performed for nerve grafting and suturing between the facial and accessory nerves. He also demonstrated the extirpation of the jugular vein and the transverse sinus for sinus thrombosis.

Dr. W. JOBSON HORNE (London) speaking of the technique of the mastoid operation referred to the relationship of the posterior bony wall of the meatus to the facial nerve, and considered that more of the wall could be cut away than was generally practised, and without injury to the facial nerve. That point had been demonstrated by Dr. Hugh Jones at a meeting of the Otological Society of the United Kingdom recently held in Liverpool. By a more efficient removal of that part of the bone better drainage was established, healing was accelerated, and a possibility of a subsequent narrowing or stenosis of the meatus was lessened. Referring to Dr. Elsworth's specimens he considered the vein to be a tributary to the petrosquamosal sinus and the accessory antrum really an aberrant mastoid cell. Whilst fully agreeing that both might have a pathological bearing he was opposed to dignifying either with a special name and thereby adding to the terminology with which the bone was already burdened.

Dr. HERBERT TILLEY (London) thought that there were far too many instruments being introduced for the less important steps in the operation and that they would come to depend less on surgical skill and a knowledge of anatomy than on mechanical appliances. He preferred separate grafts to one large one as the failure of one small one "to take" was a less evil than failure of the large and only one.

Dr. A. BRONNER (Bradford) inquired whether the heat generated by the use of the burr might be detrimental to the internal ear.

Mr. S. LODGE (Bradford) spoke of the formation of false membranes after the operation and the difficulty in keeping the *meatus sufficiently widely open.*

Dr. A. LOGAN TURNER (Edinburgh) considered that if packing was given up in the after-treatment the surgeon should inspect the ear more frequently himself and not leave it so much to the house surgeon.

Dr. R. H. WOODS (Dublin) spoke in favour of early training in the operation and the use of fewer instruments.

Professor V. DELSAUX (Brussels) spoke with reference to the after-treatment; a colleague of his had conducted the after-treatment without continuous packing with success. Personally he preferred not to lay down any hard-and-fast line.

The PRESIDENT (Dr. P. WATSON WILLIAMS, Clifton, Bristol) having briefly summed up the discussion Dr. McBRIDE and Professor HARTMANN replied. The former was in favour of Stacke's protector whilst the latter had been informed by the inventor that he had long discontinued using the instrument which he had designed.

Dr. BRONNER read a paper

On the Local Use of Formalin in the Treatment of Nasal Polypi before and after Operations on the same by the Usual Methods.

Dr. JOBSON HORNE inquired whether the possible danger of injuring the olfactory sense by the use of formalin in the treatment of nasal polypi was outweighed by the good results obtainable; he also asked whether it was desirable to intrust to patients the application of formalin of sufficient strength by means of sprays.

Dr. TILLEY thought that Dr. Bronner was making a too sweeping statement in saying that the majority of nasal polypi were caused by accessory sinus disease.

Dr. BRONNER replied that there was no objection to the application of formalin provided that the usual precautions were taken.

Dr. ARTHUR G. HAYDON (London) demonstrated photographs illustrating the familiar voice effects produced by the Singing Voice on a Suitable Medium.

FRIDAY, JULY 31ST.

Dr. F. DE HAVILLAND HALL and Dr. JOBSON HORNE opened a discussion on

The Upper Respiratory Tract as a Source of Systemic Infection.

Dr. de Havilland Hall brought forward evidence to show that typhoid fever might start in the larynx and referred to a case in his hospital practice in which the disease probably started in that organ and also to a case recorded by Dr. Watson Williams at the meeting of the British Medical Association in 1894. Infection was more likely to happen when the vitality of the laryngeal mucosa had been previously lowered by inflammatory mischief. He pointed to the initiatory symptoms of measles, influenza, and whooping-cough as clearly indicating that the virus of these diseases entered the system through the upper respiratory tract. Diphtheria was essentially a local disease at its commencement and the specific bacilli might enter at the nose, the naso-pharynx, the pharynx (which was the usual situation), or the larynx; the secondary symptoms were due to the absorption of toxic materials secreted by the bacilli during their growth. He had seen many cases of influenza in which infection appeared to have taken place in the naso-pharyngeal space and he was strongly of the opinion that adenoid vegetations rendered the individual more liable to contract influenza and many other infectious diseases. The same might be said with even greater emphasis of the faucial tonsils, and he thought that parents and others having the charge of children could not be too strongly impressed with the danger of allowing them to go about with adenoids and enlarged tonsils. Cases were quoted to show that the virus of scarlet fever might enter the system through a wound of the nasal mucous membrane. He considered that there was much to be said in favour of the view that tonsillitis was a primary infective disease of the lacunæ and that rheumatic fever was a secondary disease arising from the absorption of microbes or their products into the system. He emphasised the importance of the careful treatment of even slight tonsillar affections in view of the danger of systemic infection. Septicæmia, pyæmia, and erysipelas were shown to be diseases which certainly entered the system in many cases through the upper respiratory tract. The occurrence of primary tuberculosis of the nose, the pharynx, and the larynx, and the recognition of latent tuberculosis of the *tonsils, both faucial and pharyngeal, pointed to the possi*bility of the tubercle bacillus entering the system *viâ* the upper respiratory tract. Cases of syphilitic infection through primary sores in the nose, the naso-pharynx, the pharynx, and the larynx were mentioned.

Dr. JOBSON HORNE, after referring generally to the importance of the subject under discussion and to the vastness of the field it covered, said that he proposed only to invite consideration of a few diseases of obscure origin and insidious onset which at times—and he believed more frequently than was commonly thought—had their origin in the upper respiratory tract. The diseases specially alluded to were infective endocarditis, tuberculosis, lymphadenoma (Hodgkin's disease), and lymphosarcoma. The term "infective endocarditis" in its usually accepted and restricted sense, meaning the malignant, ulcerative, or septic phase of the disease, he said, was perhaps no longer tenable now that they knew all forms of acute endocarditis to be infective in nature. The cases, however, to which he was about to refer belonged to the more malignant and destructive variety in which the septic process was by no means confined to the heart but in which the stress of the disease was upon that organ. The part played by the faucial tonsils in rheumatic fever, and therefore in acute endocarditis, had already been submitted to them. He wished to draw attention to the larynx, a breach in the mucous membrane of which at times he had observed to be the site of entry of the parasite which brought about the destruction of the patient in malignant endocarditis. Cases were quoted and photographs shown in which the lesions in the larynx were so gross as to leave no doubt about it being the primary site of infection. The starting-point of the ulceration, he said, was in a fold of mucous membrane which commenced behind the vocal process and passed obliquely upwards and backwards to be lost between the summits of the cartilages of Santorini and Wrisberg. He found this to be a site which lent itself to infection in other diseases about which he spoke—there secretion was arrested and stagnated and there stress and strain were put upon the laryngeal mucosa so that a breach easily occurred in a weakened membrane. He referred to it as the "vulnerable spot" in the larynx. The upper respiratory tract as a source of tuberculous infection was considered under three headings. Firstly as a site of direct infection. The lesion might be the outcome of direct infection by the virus from outside the body as in primary tuberculosis of the nose, the fauces, the post-nasal adenoid tissue, the soft palate, the pharynx, the parotid gland, the tongue, the larynx, and the ear, all of such primary infections with the exception of the last being comparatively rare. On the other hand, the lesion in the upper respiratory tract might be the outcome of direct infection with sputum from the lungs, in which case, of course, the infection was a secondary one, of which tuberculosis of the larynx was a typical example. Primary tuberculosis of the larynx was so extremely rare that it was a negligible quantity. The diagnosis of such a condition for obvious reasons could only be based upon post-mortem evidence. In the course of ten years, whilst closely following the post-mortem examinations of a large general hospital, he had never met with a single case. From observations made post mortem he considered that he was in a position to make the following statements with regard to tuberculosis of the larynx: (1) when the larynx was infected with tubercle the disease was already established in the lung; (2) that by the time the disease in the larynx had advanced to ulceration the disease in the lung had advanced to cavitation; and (3) when the disease in the lung was confined *to the pure miliary form the* larynx was never infected. The deductions were that the infection of the larynx was by the sputum and that the so-called cure of laryngeal tuberculosis by means of surgical treatment was of little avail unless the disease in the lung had been arrested. Infection of the ear by the sputum he had recently dwelt upon in opening a discussion on the subject at the Otological Society of the United Kingdom. Speaking of the controversy about the relative potency of the virus of tubercle in its dry and moist forms, he said it was generally agreed that the propagation of the disease was to be attributed mainly to the particles of sputum from tuberculous patients. Cornet and his school held that the sputum was more dangerous when it became dry and pulverised. Flügge, on the *other* hand, maintained that the sputum was more infectious in its moist form, as in the spray produced in coughing and sneezing. Both the larynx and the ear were exposed to infection through the agency of an atmosphere charged with tuberculous dust, yet it was extremely rare to meet with tuberculosis primarily in the larynx by direct infection from the air inspired. It was equally rare to meet with tuberculosis in the ear starting from the external meatus. On the other hand, evidence had been adduced to prove that infection by the sputum directly from its mother soil to the larynx and to the orifice of the Eustachian tube was by no means rare. These facts, he considered, strongly supported the view advanced by Flügge. Tuberculosis when it occurred in the trachea was more marked in the posterior wall and in subjects of pulmonary tuberculosis who had become bedridden, which was explained by the prolonged contact of a tenacious agent such as sputum. Secondly, the upper respiratory tract might be a path of indirect infection in tuberculosis without any naked-eye or positive microscopic evidence being left behind to indicate the path of infection. Lymphoid tissue was the most vulnerable of all tissues to tuberculosis and yet it was most difficult to demonstrate tubercle bacilli in excised tonsils, post-nasal adenoid tissue, or lymphatic glands. That a systemic infection with tuberculosis did take place through the lymphoid ring of the upper respiratory tract was beyond question. The preceding considerations gave rise to the third proposition—the part played by the lymphoid tissue in modifying or arresting a systemic infection, which in turn brought the speaker to lymphadenoma or Hodgkin's disease. He recognised in the disease a histological entity but not a pathological one. He preferred to use the term in a comprehensive and non-committal sense. He regarded the disease as the outcome of an infection and produced evidence to prove that ulceration in the larynx at times was the site of entry of the infecting agent. The enlarged gland might be as much a manifestation of an effort on the part of the lymphatic system to prevent a disease—whether it be tuberculosis or anything else—as of disease itself. Lastly, he brought pathological evidence to show that thoracic lymphosarcoma might be part of a systemic infection and that the larynx might be the site of entry of the infecting agent. In conclusion Dr. Horne expressed the hope that one outcome of the discussion would be a wider recognition of the utility of laryngoscopy in general medicine.

Dr. J. L. GOODALE (Boston, Mass.) continued the discussion with a paper dealing with the histology of the tonsil in its relation to disease.

Dr. F. J. POYNTON (London) said that early experimental investigation in Germany demonstrated conclusively that a streptococcus might be present in the throat in diphtheria which would produce with some constancy a suppurative arthritis in animals. Dr. A. Paine and himself had made another step when they showed that a diplococcus could be isolated from a rheumatic angina which on intravenous injection would produce the lesions of rheumatic fever in the joints, heart, pleuræ and elsewhere, and which was present in the lesions of rheumatic fever in man. The stages in the process were: (1) the micro-organisms entered the fibrous framework of the tonsils and thence reached the minute blood capillaries and lymphatics and so the general circulation; and (2) the micro-organisms had been isolated from the blood in man and found in the local lesions. Thus it was established that a focus in the upper air passages might be the cause of a general infection. Local treatment of the upper air passages could only do a limited amount of good in infections of the rheumatic type, for each internal lesion was a local focus; every effort, however, should be made to arrest the process before it became generalised. It was not known why it was that micro-organisms, probably always present in the throat, suddenly became pathogenic. Infection from the throat might very probably occur without there being any appreciable local symptoms.

Dr. TILLEY limited his remarks to the part which the nose and naso-pharynx played as a source of general septic infection in two sets of circumstances. When a chronic purulent focus existed the general health might suffer in a very serious manner as a result of the constant absorption of the septic products from that focus. When operative procedures had been carried out in these regions very grave and even fatal results might ensue if due care had not been taken to provide for, and to maintain, cleanliness of the wounds.

Dr. D. R. PATERSON (Cardiff) spoke of tuberculosis arising in old cases of ozæna and also spoke of the bearing of the subject under discussion upon renal disease.

Dr. WOODS regretted that the mouth had not been included in the discussion and referred to pyorrhœa alveolaris as a source of general disturbance of health.

Dr. LOGAN TURNER spoke of obscure septic cases without obvious cause as possibly originating in some septic infection in the upper respiratory tract.

Dr. WILLIAM LAMB (Birmingham) said that the site in the larynx referred to by Dr. Jobson Horne as the "vulnerable spot" had been indicated as a site of infection in typhoid fever.

The PRESIDENT summed up the discussion and the openers replied.

TROPICAL DISEASES.

THURSDAY, JULY 30TH.

Sir PATRICK MANSON, K.C.M.G. (London), opened the discussion on

Trypanosomiasis

by briefly recapitulating the discoveries of the trypanosome parasites in men and animals. In searching for trypanosomes thin films of blood, stained by methylene blue, by thionine, or by Romanowsky's method, and examined by one-sixth of an inch objective, gave the best results. The clinical features of trypanosomiasis were usually absent in the native but in the European the disease gave rise to an undulant type of fever, accompanied by œdema, circinate erythema, muscular weakness, irritable pulse, anæmia, frequently enlarged spleen, and choroiditis, iritis, cyclitis, or optic neuritis. Sir Patrick Manson stated that possibly some of the more obscure tropical ailments, such as sleeping sickness, kala-azar, and certain forms of enlarged spleen, might be due to trypanosome parasites in the blood. The recent discovery of Castellani of trypanosomes in the cerebro-spinal fluid of persons suffering from sleeping sickness was important. The points of favour of these being associated as cause and effect were: (1) that, in Uganda at any rate, the two were frequently associated; and (2) the presence of the parasite in connexion with the nervous system. Against the idea that the trypanosome caused sleeping sickness it might be argued: (1) that, although Europeans suffered from trypanosomiasis, they did not get sleeping sickness; and (2) on the Congo and in West Africa trypanosomes had not been met with in patients suffering from sleeping sickness. The interval between infection with trypanosomes and the appearance of symptoms of sleeping sickness lasted sometimes for months or even years, but this did not completely negative the association of the parasite and the illness, for in such diseases as leprosy, malaria, and tuberculosis a similar history obtained. Sir Patrick Manson was not inclined to consider that the trypanosome in the cerebro-spinal fluid of the African was the cause of sleeping sickness. The inoculating agent might be a glossina, a tabanus, a stomoxys, or even a tick. The disease known in different parts of Africa as carrapato was produced by a tick and might or might not be a trypanosomal disease.

Dr. CUTHBERT CHRISTY (Liverpool) read a paper on

The Distribution of Sleeping Sickness and its Relation to Filaria Perstans and to Trypanosomiasis.

In Uganda, whilst serving in the Royal Commission expedition, he found sleeping sickness confined to a narrow strip of coast along the north-west and northern shores of the Victoria Nyanza lake, extending in all about 250 miles as far eastward as German East Africa. Filaria perstans was not the cause of sleeping sickness, for he met with the disease at least 100 miles beyond the extreme eastern limit of the area infected by the filaria parasite. The connexion between the presence of glossina (tsetse-fly) and sleeping sickness was such that there might be a causal relationship. It was the agricultural districts in which the parasite and the disease were more frequent, for in towns it was known that sleeping sickness was infrequent and the tsetse-fly avoided villages, objecting evidently to fæcal odours.

Dr. J. EVERETT DUTTON and Dr. J. TODD (Liverpool) communicated a paper dealing with

The Human Malady Trypanosomiasis.

They stated that they had examined 1000 persons on the Gambia and found the trypanosoma in seven persons (six natives and one quadroon). The blood infections were slight and the signs and symptoms of the disease were mild. In some cases lymphatic glands were enlarged and the spleen in young persons. Trypanosomiasis seemed to occur in both young and old people.

Dr. CHRISTY related his discovery in Uganda and its neighbourhood of the dangerous tick,

Ornithodoros Moubata (Argas Moubata, Murray),

known to the natives as the *bibo*, and previously recorded only from the Zambesi and Angola in West Africa. He found it commonly in the dust on the floors of the rest huts built for porters and in the houses of the natives. He showed specimens of the tick and gave an account of the severe symptoms occasionally following its bite and made the suggestion based upon its distribution and certain observations that it might possibly turn out to be the intermediary host of filaria perstans. Dr. Christy then read some notes furnished him by Mr. R. J. Pocock, the arachnologist to the British Museum, to whom he had submitted his specimens, in which some interesting points in connexion with his discovery were dwelt upon.

Dr. A. CASTELLANI (Florence) said that in Uganda in November, 1902, he had first noticed a trypanosome in the cerebro-spinal fluid of patients suffering from sleeping sickness and that in control cases he had never found the parasite in the fluid. It was possibly a different species of trypanosome to the trypanosoma Gambiense. The subjects of sleeping sickness seemed more liable to become infected by some parasites than were healthy natives, for in them, for instance, filaria perstans was frequently found, but the filaria was only found in the blood, never in the cerebro-spinal fluid. As horses were affected by five different forms of trypanosomiasis—namely, surra, nagana, mal de Caderas, dourine, and the form recently described by Dutton and Todd—it was possible that man might also be liable to infection by different species of trypanosomes, each causing different signs and symptoms. The mononuclear leucocytosis described by Mott and Low occurring around the vessels of the brain in sleeping sickness seemed to favour a protozoal origin of the disease. Dr. Castellani held that sleeping sickness was due to a trypanosome as (1) the parasite was constantly, or almost constantly, present in the cerebro-spinal fluid; (2) it was never found in other diseases; and (3) the pathological changes seemed to favour the conclusion that it was a trypanosomal disease.

Dr. L. W. SAMBON (London) stated that according to E. Brumpt the natives of Kilimandjero and the Galla country feared the bite of a tick which was probably the ornithodoros moubata and Dr. Christy's observation as to the peculiar
ighbouring
, however,
perstans.
The long incubation period of sleeping sickness did not negative the possible trypanosoma origin of the disease, as in several diseases due to protozoal parasites they found the same. Dr. Sambon considered that the patchy distribution of sleeping sickness along the margins of rivers and lakes agreed with the peculiar distribution of tsetse flies. He thought that the limitation of tsetse flies to the neighbourhood of water found its explanation in the feeding habits of certain freshwater fish, many of which were amphibious, retiring into burrows during the dry season and feeding at night on grain and insects. Trypanosomes were common in fish and especially amongst those living in mud. The trypanosomes of fish resembled those of mammals and the natives of
gambla, Congo, &c.) ascribed
sting of a fish or to eating fish
the trypanosoma Castellanii,
those of nagana and surra were apparently identical, still it was possible that they belonged to different strains of biological species. It had been shown that the trypanosome of nagana was modified considerably when passed through certain hosts.

Dr. G. C. LOW (London), a member of the recent commission sent to East Africa to investigate sleeping sickness, said that (1) in British Guiana he found that 50 per cent. of the aboriginal Indians had filaria perstans in their blood, but no sleeping sickness existed there; (2) in Uganda, when Dr. Low arrived there, Dr. A. D. P. Hodges and Dr. Wiggins had already demonstrated the fact that there were no cases of filaria perstans in Kavirondo, where sleeping sickness was prevalent. Filaria nocturna had its habitat in the lymphatic system, filaria perstans in the mesentery. The theory that the embryos of the filaria collected in the cerebral capillaries and thereby set up the sleeping sickness had no foundation in fact, and the theory that the poison was due to a toxin was improbable. As regards the presence of trypanosomes in the cerebro-spinal fluid causing the disease it must be remembered that many other parasites were also met with in natives besides trypanosomes, which served to complicate the diagnosis of the cause and necessitated care in arriving at a conclusion. In lower animals the pathological changes caused by trypanosomes did not justify by analogy the conclusion that these parasites in man set up the pathological conditions met with in sleeping sickness. The post-mortem macroscopic appearances of the meningeal changes in sleeping sickness closely resembled ordinary septic meningitis. On closer examination, however, it was seen that the exudation showed mononuclear leucocytoses in the perivascular spaces in the former and polymorphonuclear leucocytoses in the latter and not in the perivascular spaces specially. Regarding the theory of Dr. Christy that argas moubata was the host of filaria perstans it might be mentioned that Dr. C. W. Daniels had shown that this parasite did not exist in British Central Africa. In British Guiana, on the other hand, there was no argas moubata, but filaria perstans were plentiful. Dr. Sambon's statement that the tsetse fly was always found near water was at variance with Mr. F. J. Jackson's observations that the fly was met with in areas that were perfectly dry and covered with scanty bush.

Captain LEONARD ROGERS, I.M.S., objected to the view of regarding kala-azar as a trypanosome disease. He thought it impossible to recognise trypanosomes by so-called involution forms. He had examined several hundreds of cases of kala-azar but had never found a trypanosome. A characteristic feature in kala-azar was the peculiar melanotic pigmentation invariably found in the organs. Such a pigmentation was proof of an endoglobular parasite. The trypanosome lived in the plasma. In surra no melanotic pigmentation was produced by the trypanosome.

Fleet Surgeon P. W. BASSETT-SMITH, R.N., read a paper on

Five Cases of Abscess of the Liver.

Three of the cases recorded were operated upon by Surgeon G. Kirker, R.N., successfully by abdominal or trans-thoracic incisions. All the patients had had dysentery previously. Fleet Surgeon Bassett Smith also drew attention to the importance of recognising the presence of leucocytosis as an aid in the diagnosis of the presence of pus.

Mr. JAMES CANTLIE (London) stated that during the past two years he had operated upon ten cases of abscess of the liver, and at one period, in August, 1902, had seven cases of abscess of the liver at one time under his care, showing how much more prevalent hepatic abscesses were in England than might be expected. He had now used the trocar and cannula and syphon drainage in some 50 cases of this disease and he strongly condemned trans-thoracic incision or laparotomy for *deep-seated* abscess of the liver as being over-heroic and likely to cause young or inexperienced surgeons to put off operation until too late. He had seen so much of this lately that he regretted that teachers of surgery should advocate an operation which their pupils would not care to undertake (until too late) and condemn a simple operation which was more efficient, safer, and could be done by a medical man single-handed. The last point was one of great importance as abscesses of the liver were frequent in out-of-the-way parts of the world, where hospitals were but ill equipped and where neither nurses nor skilled assistance could be obtained. To tell a man in such a position that the only operation for abscess of the liver was opening the pleura, excising a piece of rib, opening the peritoneal cavity, and then searching for pus deeply seated in the liver tissue was to condemn the practitioner to non-interference or his patient to death.

Captain ROGERS read a paper on

Biliary Abscesses of the Liver, with an Operation.

By biliary abscess Captain Rogers meant abscesses in the liver within the bile ducts, sometimes called "suppurative cholangitis." The difficulty of diagnosis in such cases was great. The history given was usually that of enlarged liver, fever, and repeated attacks of jaundice. In one case in Calcutta Captain Rogers found the gall-bladder filled with calculi and a large number also in the right hepatic duct; these were removed and the wound was drained but the patient died. Post mortem the bile-ducts were full of pus which had burrowed backwards and upwards, invading the right lung. He considered that were cases of the kind operated upon at a fairly early stage good results might be anticipated.

FRIDAY, JULY 31ST.

Discussion on Leprosy.
